BASICS OF CHEMISTRY

1. CLASSIFICATION OF MATTER

1.1 Physical classification: It is based on physical state under ordinary conditions of temperature and pressure, matter is classified into the following three types:

(a) Solid **(b) Liquid** **(c) Gas**

(a) Solid: A substance is said to be solid if it possesses a definite volume and a definite shape

E.g. sugar, iron, gold, wood etc.

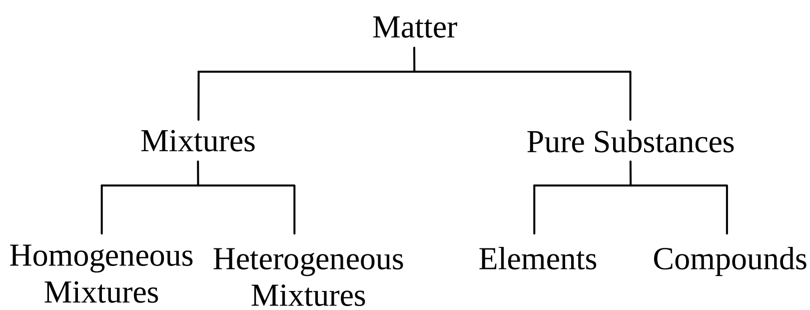
(b) Liquid: A substance is said to be liquid if it possesses a definite volume but not definite shape. They take up the shape of the vessel in which they are put.

E.g. water, milk, oil, mercury, alcohol etc.

(c) Gas: A substance is said to be gas if it neither possesses a definite volume nor a definite shape. This is because they fill up the whole vessel in which they are put.

E.g. hydrogen(H_2), oxygen(O_2), carbon dioxide(CO_2), etc.

1.2 Chemical classification:



On the basis of chemical nature matter is classified into the following two types :

(a) Pure Substance **(b) Mixture**

(a) Pure Substance: When all constituent particles of a substance are same in chemical nature, it is said to be a pure substance. Two type of pure substances:

(i) Element **(ii) Compound**

(i) Element: an element consist of only one type of atoms. These particles may exist as Atoms or molecules. E.g. O_2, P_4, S_8, etc.

(ii) Compound: When two or more atoms of different elements combine together in a definite ratio. E.g. water, ammonia, carbon dioxide, sugar, etc.

(b) Mixture: A mixture contains many types of particles. A mixture contains particles of two or more pure substances which may be present in it in any ratio. Hence, their composition is variable. Pure substances forming mixture are called its components. Many of the substances present around you are mixtures. For example, sugar solution in water, air, tea, etc., are all mixtures. Two types of mixtures:

(i) Homogeneous mixture **(ii) Heterogeneous mixture**

(i) **Homogeneous mixture:** The components completely mix with each other. This means particles of components of the mixture are uniformly distributed throughout the bulk of the mixture and its composition is uniform throughout. E.g.: Sugar solution, air

(ii) **Heterogeneous mixture:** In a heterogeneous mixture, the composition is not uniform throughout and sometimes different components are visible. E.g.: mixtures of salt and sugar, grains and pulses along with some dirt (often stone pieces)

2. INTRODUCTION:

There are a large number of objects around us which we can see and feel. It was John Dalton who firstly developed a theory on the structure of matter, later on which is known as Dalton's atomic theory.

2.1. DALTON'S ATOMIC THEORY:

(i) Each element is composed of extremely small particles called atoms which can take part in chemical combination.

(ii) All atoms of a given element are identical i.e., atoms of a particular element are all alike but differ from atoms of other elements.

(iii) Atoms of different elements possess different properties (including different masses).

(iv) Atoms are indestructible i.e., atoms are neither created nor destroyed in chemical reactions.

(v) Atoms of elements combine to form molecules and compounds are formed when atoms of more than one element combine.

(vi) In a given compound, the relative number and kind of atoms is constant.

2.2. **Atomic mass:** It is the average relative mass of atom of element as compared with times the mass of an atom of carbon-12 isotope.

$$\text{Atomic mass } = \frac{\text{Average mass of an atom}}{1/12 \times \text{Mass of an atom of } C^{12}}$$

2.3. **Gram atomic mass (GAM):** Atomic mass of an element expressed in grams is called Gram atomic mass or gram atom or mole atom.

(i) Number of gram atoms = $\frac{\text{Mass of an element}}{\text{GAM}}$

(ii) Mass of an element in g = No. of gram atoms × GAM

(iii) Number of atoms in 1 GAM = 6.02×10^{23}

Number of atoms in a given substance = No. of gram atoms × 6.02×10^{23}

(iv) Number of atoms in 1 g of element = $\frac{\text{Mass}}{\text{GAM}}$

(v) Mass of one atom of the element (in g) = $\frac{\text{GAM}}{6.02 \times 10^{23}}$

2.4. Molecular mass: Molecular mass of a molecule, of an element or a compound may be defined as a number which indicates how many times heavier is a molecule of that element or compound as compared with $\frac{1}{12}$ of the mass of an atom of carbon-12. Molecular mass is also expressed in a.m.u.

$$\text{Molecular mass} = \frac{\text{Mass of one molecule of the substance}}{1/12 \times \text{Mass of one atom of C-12}}$$

Actual mass of one molecule = Mol. mass (in amu) × 1.66 × 10^{-24} g

Molecular mass of a substance is the additive property and can be calculated by adding the atomic masses of atoms present in one molecule.

2.5. Gram molecular mass (GMM) : Molecular mass of an element or compound when expressed in g is called its gram molecular mass, gram molecule or mole molecule.

$$\text{Number of gram molecules} = \frac{\text{Mass of substance}}{\text{GMM}}$$

Mass of substance in g = No. of gram molecules × GMM

Element	**R.A.M. (Relative Atomic Mass)**	**Mass of one atom**	**Gram Atomic mass /weight**
N	14	14 amu	14 gm
He	4	4 amu	4 gm
C	12	12 amu	12 gm

2.6. Mole

One mole of any substance contains a fixed number (6.023×10^{23}) of any type of particles (atoms or molecules or ions) and has a mass equal to the atomic or molecular weight, in grams. Thus it is correct to refer to a mole of helium, a mole of electrons or a mole of any ion, meaning respectively Avogadro's number of atoms, electrons or ions.

Methods of Calculations of mole:

(1) If no. of some species is given, then no. of moles = $\frac{\text{Given no}}{N_A}$

(2) If weight of a given species is given, then no. of moles = $\frac{\text{Given wt.}}{\text{Atomic wt.}}$ (for atoms),

or = $\frac{\text{Given wt.}}{\text{Molecular wt.}}$ (for molecules)

(3) If volume of a gas is given along with its temperature (T) and pressure (P).

$PV = nRT$ (n : Number of moles of gas)

P (Pressure of gas): Pressure of the gas is the force exerted by the gas per unit area of the walls of the container in all directions.

Thus, Pressure (P) $= \frac{\text{Force(F)}}{\text{Area(A)}} = \frac{\text{Mass(m)} \times \text{Acceleration(a)}}{\text{Area(A)}}$

Name	Symbol	Value
Bar	bar	1 bar = 10^5 Pa
Atmosphere	atm	1 atm = 1.01325×10^5 Pa
Torr	Torr	1 Torr = $\frac{101325}{760}$ Pa × 133.322 Pa
millimeter of mercury	mm Hg	1 mm Hg = 133.322 Pa

V (Volume of gas): Volume is expressed in liters (L), milliliters (mL) or cubic centimeters (cm^3), cubic meters (m^3) .

$1\ m^3 = 10^3\ dm^3 = 10^6 cm^3 = 10^6\ mL = 10^3\ L$

T (Temperature of gas): S.I. unit of temperature is Kelvin (K).

$$T(K) = t(^oC) + 273.15$$

R (Universal gas constant) : Values of R = 0.082 $LatmK^{-1}mol^{-1}$

=8.314 $JK^{-1}mol^{-1}$

=1.987 $CalK^{-1}mol^{-1}$

Note : 1 mole of atom is also termed as 1 g–atom

1 mole of ions is also termed as 1 g–ion

1 mole of molecule is also termed as 1 g–molecule

Ans. 1.9×10^6 years (approx)

Sol. 10^{10} grains are distributed in 1 second

6.02×10^{23} grains are distributed in $\frac{6.02 \times 10^{23}}{10^{10}}$ sec = $\frac{6.02 \times 10^{23}}{10^{10} \times 60 \times 60 \times 24 \times 365}$ years

= 1.9×10^6 years (approx.)

Ex.2 How many atoms are there in 100 amu of He ?

Ans. 25

Sol. We know that, 1 amu = $\frac{1}{12}$ × weight of one ^{12}C atom

or weight of one ^{12}C atom = 12 amu (at. wt. of C = 12 amu).

Similarly, as the atomic weight of He is 4

weight of one He atom = 4 amu.

Thus, the number of atoms in 100 amu of He = $\frac{100}{4}$ = 25.

Ex.3 The weight of one atom of Uranium is 238 amu. Its actual weight in gm is ______ :

Ans. 396.74×10^{-4}

Sol. Weight of aone atom = 238 amu

$= 238 \times 1.667 \times 10^{-24}$

$= 396.74 \times 10^{-4}$

_Ex.4_ Calculate the number of molecules in a drop of water weighing 0.09 g.

Ans. 3.01×10^{21} molecules of H_2O

Sol. number of mole = $\dfrac{0.09}{18}$

so number of molecules = $\dfrac{0.09}{18} \times N_A = \; = 3.01 \times 10^{21}$.

_Ex.5_ A sample of ethane has the same mass as 10.0 million molecules of methane. How many C_2H_6 molecules does the sample contain?

Ans. 5.34×10^6

Sol. Let the number of C_2H_6 molecules in the sample be n. As given, mass of C_2H_6 = mass of 10^7 molecules of CH_4

$$\frac{n}{N_A} \times \text{mol. wt. of } C_2H_6 = \frac{10^7}{N_A} \times \text{mol. wt. of } CH_4$$

$$\frac{n}{N_A} \times 30 = \frac{10^7}{N_A} \times 16$$

$n = 5.34 \times 10^6$.

_Ex.6_ If, from 10 moles NH_3 and 5 moles of H_2SO_4 , all the H-atoms are removed in order to form H_2 gas, then find the number of H_2 molecules formed.

Ans. 20 N_A

Sol. 10 mole NH_3 have mole of 'H' atom = 10×3

5 mole of H_2SO_4 have mole of 'H' atom = 10

Total mole of 'H' atom = 40

mole of H_2 = 20

_Ex.7_ The weight of 350 mL of a diatomic gas at 0ºC and 2 atm pressure is 1 g. The weight of one atom is :

Ans. 16 amu

Sol. PV = nRT; $\quad n = \dfrac{PV}{RT}$

$$n = \frac{2 \times 0.350}{0.0821 \times 273} =$$

$$n = \frac{\text{Weight}}{\text{Atomic mass}}$$

Atomic mass = 16 amu

Ex.8 Oxygen is present in a 1-litre flask at a pressure of 7.6×10^{-10} mm of Hg at 0ºC. Calculate the number of oxygen molecules in the flask.

Ans. 0.44×10^{-13} .

Sol. Pressure = 7.6×10^{-10} mm

$= 0.76 \times 10^{-10}$ cm

= atm (1 atom = 76 cm) = 10^{-12} atm.

Volume = 1 litre, R = 0.0821 lit. atm/K/mole, temperature = 273 K.

We know that PV = nRT or n = $\dfrac{pV}{RT}$

$$n = \frac{10^{-12} \times 1}{0.082 \times 273} = 0.44 \times 10^{-13}$$

Sol. Moles of O_2 = Moles of X(unknown gas)

$$\frac{1}{32} = \frac{2.375}{M_X}$$

$M_X = 76$

(A) 6.023×10^{23} (B) $\dfrac{1}{9.108} \times 10^{31}$ (C) $\dfrac{6.023}{9.108} \times 10^{54}$ (D) $\dfrac{1}{9.108 \times 6.023} \times 10^{8}$

3. LAWS OF CHEMICAL COMBINATION:

Antoine Lavoisier, John Dalton and other scientists formulate certain laws concerning the composition of matter and chemical reactions. These laws are known as the law of chemical combination.

3.1 THE LAW OF CONSERVATION OF MASS:

It is given by Antoine Lavoisier.
In a chemical change total mass remains conserved that is mass before reaction is always equal to mass after reaction.
Example:

$$H_2\,(g) + \frac{1}{2}O_2\,(g) \rightarrow H_2O(\ell)$$

	$H_2\,(g)$	$O_2\,(g)$	$H_2O(\ell)$
Before reaction initially	1 mole	$\frac{1}{2}$ mole	
After the reaction	0	0	1 mole

mass before reaction = mass of 1 mole H_2 (g) + mass of $\frac{1}{2}$ mole O_2 (g)

= 2 + 16 = 18 g

mass after reaction = mass of 1 mole water = 18 g

3.2 LAW OF CONSTANT OR DEFINITE PROPORTION:

It is given by Proust. All chemical compounds are found to have constant composition irrespective of their method of preparation or sources.

Example: In water (H_2O), Hydrogen and Oxygen combine in 2 : 1 molar ratio, the ratio remains constant whether it is tap water, river water or sea water or produced by any chemical reaction.

Ex.10 1.80 g of a certain metal burnt in oxygen gave 3.0 g of its oxide. 1.50 g of the same metal heated insteam gave 2.50 g of its oxide. Show that these results illustrate the law of constant proportion.

Sol. In the first sample of the oxide,

wt. of metal = 1.80 g,

wt. of oxygen = (3.0 – 1.80) g = 1.2 g

$$\frac{\text{wt. of metal}}{\text{wt. of oxygen}} = \frac{1.80\text{g}}{1.2\text{g}} = 1.5$$

In the second sample of the oxide,

$$\frac{\text{wt. of metal}}{\text{wt. of oxygen}} = \frac{1.50\text{g}}{1\text{g}} = 1.5$$

Thus, in both samples of the oxide the proportions of the weights of the metal and oxygen are fixed. Hence, the results follow the law of constant proportion.

3.3 THE LAW OF MULTIPLE PROPORTIONS:

It is given by Dalton.

When one element combines with the other element to form two or more different compounds, the mass of one element, which combines with a constant mass of the other, bear a simple ratio to one another.

Note: Simple ratio here means the ratio between small natural numbers, such as 1: 1, 1: 2, 1: 3, Later on this simple ratio becomes the valency and then oxidation state of the element.

Example: Carbon and Oxygen when combine, can form two oxides, CO (carbon monoxide), CO_2(Carbon dioxides)

In CO, 12 g carbon combined with 16 g of oxygen.

In CO_2, 12 g carbon combined with 32 g of oxygen.

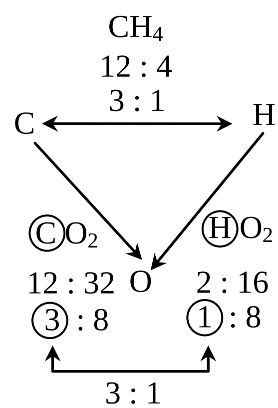
Thus, we can see the mass of oxygen which combine with a constant mass of carbon (12 g) bear simple ratio of 16 : 32 or 1 : 2.

3.4 LAW OF RECIPROCAL PROPORTION:

It is given by Richter.

The ratio of the weights of two elements A and B which combine separately with a fixed weight of the third element C is either the same or simple ratio of the weights in which A and B combine directly with each other.

Example:



Ex.11 Ammonia contains 82.35% of nitrogen and 17.65% of hydrogen. Water contains 88.90% of oxygen and11.10% of hydrogen. Nitrogen trioxide contains 63.15% of oxygen and 36.85% of nitrogen. Show that these data illustrate the law of reciprocal proportions.

Sol. In NH_3, 17.65g of H combine with N = 82.35g

1 g of H combine with N $= \dfrac{82.35}{17.65}$ g = 4.67 g

In H_2O, 11.10 g of H combine with O = 88.90 g

1 g of H combine with O $= \dfrac{88.90}{11.10}$ g = 8.01g

Ratio of the weights of N and O which combine with fixed weight (=1g) of H

= 4.67 : 8.01 = 1 : 1.7

In N_2O_3, ratio of weights of N and O which combine with each other =36.85 : 63.15

= 1 : 1.7

Thus the two ratios are the same. Hence it illustrates the law of reciprocal proportions.

3.5 GAY-LUSSAC'S LAW OF COMBINING VOLUME:

According to him elements combine in a simple ratio of atoms, gases combine in a simple ratio of their volumes provided all measurements should be done in the same temperature and pressure

$$H_2(g) + Cl_2(g) \longrightarrow 2HCl$$

1 vol 1 vol 2 vol

3.6 AVOGADRO'S H YPOTHESIS:

Equal volumes of polyatomic all gases have equal number of molecules (not atoms) at same temperature and pressures conditions.

S.T.P. (Standard Temperature and Pressure)

At S.T.P. condition:

Temperature = 0°C or 273 K

Pressure = 1 bar

and volume of one mole of gas at STP is found to be equal to 22.7litres which is known as molar volume.

4. STOICHIOMETRY AND STOICHIOMETRIC CALCULATIONS

The word 'stoichiometry' is derived from two Greek words — *stoicheion*(meaning, *element*) and *metron*(meaning, *measure*).Stoichiometry, thus, deals with the calculation of masses (sometimes volumes also) of the reactants and the products involved in a chemical reaction

Example: When potassium chlorate ($KClO_3$) is heated it gives potassium chloride (KCl) and oxygen (O_2).

$KClO_3 \xrightarrow{\Delta} KCl + O_2$ (unbalanced chemical equation)

$2KClO_3 \xrightarrow{\Delta} 2\,KCl + 3O_2$ (balanced chemical equation)

- Remember a balanced chemical equation is one which contains an equal number atoms of each element on both sides of equation.

4.1 Interpretation of balanced chemical equations:

Once we get a balanced chemical equation then we can interpret a chemical equation by following ways

(a) Mass - mass analysis
(b) Mass - volume analysis
(c) Mole - mole analysis

(a) Mole - mole analysis :

This analysis is very much important for quantitative analysis point of view.

Now consider again the decomposition of $KClO_3$.

$$2\,KClO_3 \longrightarrow 2\,KCl + 3O_2$$

In very first step of mole-mole analysis you should read the balanced chemical equation like **2 moles $KClO_3$ on decomposition gives you 2 moles KCl and 3 moles O_2** and from the stoichiometry of reaction we can write

$$\frac{\text{Moles of } KClO_3}{2} = \frac{\text{Moles of } KCl}{2} = \frac{\text{Moles of } O_2}{3}$$

Now for any general balance chemical equation like

a A + b B $\longrightarrow$ c C + d D

you can write.

$$\frac{\text{Moles of A reacted}}{a} = \frac{\text{Moles of B reacted}}{b} = \frac{\text{Moles of C produced}}{c} = \frac{\text{Moles of D produced}}{d}$$

(b) Mass - mass analysis :

Consider the reaction 2 $KClO_3 \longrightarrow 2KCl + 3O_2$ According to stoichiometry of the reaction

or $\frac{\text{Mass of } KClO_3}{\text{Mass of } KCl} = \frac{2\times122.5}{2\times74.5}$ $\quad\quad$ $\frac{\text{Mass of } KClO_3}{\text{Mass of } O_2} = \frac{2\times122.5}{3\times32}$

Ex.12 Consider the balanced reaction

$2Cl_2O_7 \longrightarrow 4ClO_2 + 3O_2$ (Cl = 35.5)

What can be concluded from the coefficients of species in this balanced equation?

(A) For this reaction, exactly 2 g of Cl_2O_7 must be taken to start the reaction

(B) For this reaction, exactly 2 mol of Cl_2O_7 must be taken to start the reaction

(C) Mole ratio of Cl_2O_7 , ClO_2 and O_2 during a chemical reaction at any instant are 2, 4 and 3 respectively

(D) The ratio of change in number of moles of Cl_2O_7 , ClO_2 and O_2 is 2 : 4 : 3

Ans. (D)

Sol. It follows directly from definition of stoichiometry.

Ex.13 Calculate the weight of iron which will be converted into its oxide by the action of 36 g of steam.

(Given : $3Fe + 4H_2O \longrightarrow Fe_3O_4 + H_2$)

Ans. 84 g

Sol. Mole ratio of reaction suggests,

Mole of Fe = $\frac{3}{4}$ mol of H_2O

$= \frac{3}{4}\times\frac{36}{18} = \frac{3}{2}$

wt. of Fe = $\frac{3}{2}\times56 = 84$ g

Ex.14 When Dinitrogen pentaoxide (N_2O_5, a white solid) is heated, it decomposes into nitrogen dioxide and oxygen.

If a sample of N_2O_5 produces 1.6 g O_2, then how many grams of NO_2 are formed ?

$$N_2O_5(s) \longrightarrow NO_2(g) + O_2(g) \qquad \text{(not balanced)}$$

(A) 9.2 g (B) 4.6 g (C) 2.3 g (D) 18.4 g

Ans. (A)

Sol. $N_2O_5(s) \longrightarrow 2NO_2(s) + \frac{1}{2}O_2$ (Balanced reaction)

$$\frac{\text{Mole of } O_2}{1/2} = \frac{\text{Mole of } NO_2}{2}$$

$$\frac{1.6}{32} \times 2 \times 2 = \text{Mole of } NO_2 = 0.2$$

wt of NO_2 = 0.2 × 46 = 9.2 g.

(c) Mass - volume analysis :

Now again consider decomposition of $KClO_3$

$$2\,KClO_3 \longrightarrow 2KCl + 3O_2$$

mass volume ratio : 2 × 122.5 g : 2 × 74.5 g : 3 × 22.4 L at STP

we can use two relation for volume of oxygen

$$\frac{\text{Mass of } KClO_3}{\text{volume of } O_2 \text{at STP}} = \frac{2\times122.5\text{g}}{3\times22.4\text{L}} \qquad \text{....(i)}$$

and $$\frac{\text{Mass of KCl}}{\text{volume of } O_2 \text{ at STP}} = \frac{2\times74.5\text{g}}{3\times22.4\text{L}} \qquad \text{....(ii)}$$

Ex.15 When oxygen gas is passed through Siemen's ozoniser, it completely gets converted into ozone gas. The volume of ozone gas produced at 1 atm and 273K, if initially 96 g of oxygen gas was taken, is :

(A) 44.8 L (B) 89.6 L (C) 67.2 L (D) 22.4 L

Ans. (A)

Sol. $3O_2 \longrightarrow 2O_3$

Mole = $\frac{96}{32}$ = 3 mole = 2

Volume of O_3 gas at 1 atm and 273K = 2 × 22.4 = 44.8 L

Do yourself-2:

1. Assuming 100% yield of the reaction, how many moles of $NaHCO_3$ will produce 448 mL of CO_2 gas at STP according to the reaction :

$$NaHCO_3 \xrightarrow{\Delta} Na_2CO_3 + CO_2 + H_2O \text{ (unbalanced)}$$

(A) 0.04 (B) 0.4 (C) 4 (D) 40

2. Calculate the residue obtained on strongly heating 2.76 g Ag_2CO_3.

$$Ag_2CO_3 \xrightarrow{\Delta} 2Ag + CO_2 + \frac{1}{2}O_2$$

3. For the reaction $2P + Q \longrightarrow R$, 4 mol of P and excess of Q will produce :

(A) 8 mol of R (B) 5 mol of R (C) 2 mol of R (D) 1 mol of R

4. If 1.5 moles of oxygen combine with Al to form Al_2O_3, the weight of Al used in the reaction is:

(A) 27 g (B) 40.5 g (C) 54g (D) 81 g

5. How many liters of CO_2 at STP will be formed when 0.01 mol of H_2SO_4 reacts with excess of Na_2CO_3 .

$$Na_2CO_3 + H_2SO_4 \longrightarrow Na_2SO_4 + CO_2 + H_2O$$

(A) 22.7 L (B) 2.27 L (C) 0.227 L (D) 1.135 L

4.2 LIMITING REAGENT:

Many a time, reactions are carried out with the amounts of reactants that are different than the amounts as required by a balanced chemical reaction. In such situations, one reactant is in more amount than the amount required by balanced chemical reaction. The reactant which is present in the least amount gets consumed after sometime and after that further reaction does not take place whatever be the amount of the other reactant. Hence, the reactant, which gets consumed first, limits the amount of product formed and is, therefore, called the limiting reagent.

The reactant which consumed first into the reaction when we are dealing with balance chemical equation then if number of moles of reactants are not in the ratio of stoichiometric coefficient of balanced chemical equation, then there should be one reactant which should be limiting reactant.

Ex.16 Six mole of Na_2CO_3 is reacted with 4 moles of HCl solution. Find the volume of CO_2 gas produced at STP. The reaction is

$$Na_2CO_3 + 2\,HCl \longrightarrow 2\,NaCl + CO_2 + H_2O$$

Sol.

From the reaction :	Na_2CO_3	+ 2 HCl	$\longrightarrow$	$2\,NaCl + CO_2 + H_2O$
gives moles	3 mol	6 mol		
given mole ratio	1 :	2		
Stoichiometric coefficient ratio	1 :	2		

See here given number of moles of reactants are not in stoichiometric coefficient ratio. Therefore there should be one reactant which consumed first and becomes limiting reagent.

But the question is how to find which reactant is limiting, it is not very difficult you can easily find it. According to the following method.

How to find limiting reagent:

Step : I

Divide the given moles of reactant by the respective stoichiometric coefficient of that reactant.

Step : II

See for which reactant this division comes out to be minimum. The reactant having minimum value is limiting reagent.

Step : III

Now once you find limiting reagent then your focus should be on limiting reagent

From	Step I & II	Na_2CO_3	HCl
		$\frac{6}{1} = 6$	$\frac{4}{2} = 2$ (Division in minimum)

$\therefore$ HCl is limiting reagent

From Step III

From $\frac{\text{Mole of HCl}}{2} = \frac{\text{Mole of } CO_2 \text{ produced}}{1}$

$\therefore$ Mole of CO_2 produced = 2 moles

$\therefore$ Volume of CO_2 produced at S.T.P. = $2 \times 22.7 = 45.4$ L

Ex.17 In the reaction $4A + 2B + 3C \longrightarrow A_4B_2C_3$ what will be the number of moles of product formed, starting from 2 moles of A, 1.2 moles of B & 1.44 moles of C :

(A) 0.5 (B) 0.6 (C) 0.48 (D) 4.64

Ans. (C)

Sol.

	4A	+ 2B	+ 3C $\longrightarrow$	$A_4B_2C_3$
Initial mole	2	1.2	1.44	0
final mole			0	0.48

C is limiting reagent.

moles of $A_4B_2C_3$ is 0.48.

Ex.18 A 5 g mixture of SO_2 and O_2 gases is reacted to form SO_3 gas. What should be the mass ratio of SO_2 and O_2 gases in mixture to obtain maximum amount of SO_3 gas :

(A) 4 : 1 (B) 3 : 2 (C) 2 : 3 (D) 1 : 4

Ans. (A)

Sol. For maximum amount of product, the reactants should be present in their stoichiometric ratio.

$$2SO_2\,(g) + O_2\,(g) \longrightarrow 2SO_3\,(g)$$

mass $\quad x \quad\quad 5 - x$

mole $\quad \frac{x}{64} \quad\quad \frac{5-x}{32}$

So, $\frac{\left(\frac{x}{64}\right)}{\left(\frac{5-x}{32}\right)} = 2 : 1$

Therefore, x = 4

$m_{SO2} : m_{O2} = 4 : 1$.

Ex.19 Calculate the weight of FeO from 4 g VO and 5.75 g of Fe_2O_3. Also report the limiting reactant.

$$VO + Fe_2O_3 \longrightarrow FeO + V_2O_5$$

Ans. Weight of FeO formed = 5.17 g

Sol.

Balanced equation	$2VO$ +	$3Fe_2O_3 \longrightarrow$	$6FeO$	+	V_2O_5
Moles before reaction	$\frac{4}{67}$	$\frac{5.75}{160}$	0		0
=	0.5970	0.03590			
Moles after reaction	(0.05970–0.0359)	0	$\left(\frac{6}{5}\times 0.0359\right)$		$\left(\frac{1}{3}\times 0.0359\right)$

As 2 moles of VO react with 3 moles of Fe_2O_3

$\therefore$ 0.05970 g moles of VO = $\frac{3}{2}$ 0.05970 = 0.08955 moles of Fe_2O_3

Moles of Fe_2O_3 available = 0.0359 only

Hence, Fe_2O_3 is the limiting reagent.

Moles of FeO formed = $\frac{6}{3}$ 0.0359

$\therefore$ Weight of FeO formed = 0.0359 × 2 × 72 = 5.17 g

$$\left(\frac{n_{FeO}}{n_{Fe_2O_3}} = \frac{6}{3}\right) \Rightarrow n_{FeO} = \frac{6}{3}\times n_{Fe_2O_3}$$

5. The mass of Na_2SO_4 produced from 196 gram of H_2SO_4 and 1 mole of NaOH.

(A) 49 g (B) 98 g (C) 61 g (D) 34.3 g

4.3 PRINCIPLE OF ATOM CONSERVATION (POAC):

Infect POAC is nothing but the conservation of mass, expressed before in the concepts of atomic theory. And if atoms are conserved, moles of atoms shall also be conserved.
The principle is fruitful for the students when they don't get the idea of balanced chemical equation in the problem.
This principle can be under stand by the following example.
Consider the decomposition of $KClO_3$ (s) $\rightarrow$KCl (s) + O_2 (g) (unbalanced chemical react ion)
Apply the principle of atom conservation (POAC) for K atoms.
Moles of K atoms in reactant = moles of K atoms in products
or moles of K atoms in $KClO_3$ = moles of K atoms in KCl
Now, since 1 molecule of $KClO_3$ contains 1 atom of K
or 1 mole of $KClO_3$ contains 1 mole of K, similarly 1 mole of KCl contains 1 mole of K
Thus, moles of K atoms in $KClO_3$ = 1 × moles of $KClO_3$
and moles of K atoms in KCl = 1 × moles of KCl
$\therefore$ moles of $KClO_3$ = moles of KCl

or $$\frac{\text{wt. of } KClO_3 \text{in g}}{\text{mol. wt. of } KClO_3} = \frac{\text{wt. of KCl in g}}{\text{mol. wt. of KCl}}$$

* The above equation gives the mass-mass relationship between $KClO_3$ and KCl which is important in stoichiometric calculations.
Again, applying the principle of atom conservation for O atoms,
moles of O in $KClO_3$ = 3 × moles of $KClO_3$
moles of O in O_2 = 2 × moles of O_2
$\therefore$ 3 × moles of $KClO_3$ = 2 × moles of O_2

or $$\frac{\text{wt. of } KClO_3}{\text{mol. wt. of } KClO_3} = 2 \times \frac{\text{vol. of } O_2 \text{ at NTP}}{\text{standard molar vol.(22.4 lt)}}$$

* The above equations thus give the mass-volume relationship of reactants and products.

Ex.20 27.6g K_2CO_3 was treated by a series of reagents so as to convert all of its carbon to $K_2Zn_3[Fe(CN)_6]_2$. Calculate the weight of the product.
[mol. wt. of K_2CO_3 = 138 and mol. wt. of $K_2Zn_3[Fe(CN)_6]_2$ = 698]

Ans. 11.6 g

Sol. Here we have not knowledge about series of chemical reactions but we known about initial reactant and final product accordingly

$$K_2CO_3 \xrightarrow[\text{Steps}]{\text{Several}} K_2Zn_3[Fe(CN)_6]_2$$

Since C atoms are conserved, applying POAC for C atoms,
Moles of C in K_2CO_3 = moles of C in $K_2Zn_3[Fe(CN)_6]_2$
1 × moles of K_2CO_3 = 12 × moles of $K_2Zn_3[Fe(CN)_6]_2$
($\because$ 1 mole of K_2CO_3 contains 1 moles of C)

$$\frac{\text{wt. of } K_2CO_3}{\text{mol. wt. of } K_2CO_3} = 12\,\frac{\text{wt. of the product}}{\text{mol. wt. of product}}$$

wt. of $K_2Zn_3[Fe(CN)_6]_2$ = $\frac{27.6}{138}\ \frac{698}{12}$ = 11.6 g

Ex.21 In a gravimetric determination of P of an aqueous solution of dihydrogen phosphate in $H_2PO_4^-$ is treated with a mixture of ammonium and magnesium ions to precipitate magnesium ammonium phosphate, $Mg(NH_4)PO_4.6H_2O$. This is heated and decomposed to magnesium pyrophosphate, $Mg_2P_2O_7$. A solution of $H_2PO_4^-$ yielded 2.054 g of ($Mg_2P_2O_7$). What weight of NaH_2PO_4 was present originally?

Ans. 2.22 g

Sol. $NaH_2PO_4 + Mg^{2+} + NH_4^+ + \longrightarrow Mg(NH_4)PO_4.6H_2O \xrightarrow{\Delta} Mg_2P_2O_7$

As P atoms are conserved, applying POAC for P atoms, moles of P in NaH_2PO_4 = Moles of P in $Mg_2P_2O_7$

$\Rightarrow 1 \times$ Moles of $NaH_2PO_4 = 2 \times$ Moles of $Mg_2P_2O_7$

$$\therefore \quad \frac{W_{NaH_2PO_4}}{M_{NaH_2PO_4}} = 2 \times \frac{W_{Mg_2P_2O_7}}{M_{Mg_2P_2O_7}} \Rightarrow \frac{W_{NaH_2PO_4}}{120} = 2 \times \frac{2.054}{222}$$

$$\therefore \quad W_{NaH_2PO_4} = 2.22 \text{ g}$$

4.4 PERCENTAGE YIELD:

In general, in any chemical reaction, the amount of product formed is always less than the calculated amount due to reversibility in the chemical reaction. Therefore, yield of a chemical reaction (Y) comes into picture and is given by :

$$\text{The percentage yield of product} = \frac{\text{actual yield}}{\text{the theoretical maximum yield}} \times 100$$

Ex.22 In a certain operation 358 g of $TiCl_4$ is reacted with 96 g of Mg. Calculate % yield of Ti if 32 g of Ti is actually obtained [At. wt. Ti = 48, Mg = 24]

(A) 35.38 % (B) 66.6 % (C) 100 % (D) 60 %

Ans. (A)

Sol.

	$TiCl_4$ +	$2Mg$ $\longrightarrow$	Ti +	$2MgCl_2$
Initial mole	$\frac{358}{190} = 1.88$	$\frac{96}{24} = 4$		
final mole	0	$4 - 2 \times 1.88$	1.88	2×1.88

wt of Ti obtained $= \frac{358}{190} \times 48$

$$\% \text{ yield} = \frac{32 \times 100}{\frac{358 \times 48}{190}} = 35.38 \%$$

Ex.23 0.05 mole of $LiAlH_4$ in ether solution was placed in a flask containing 74g (1 mole) of t-butyl alcohol. The product $LiAlHC_{12}H_{27}O_3$ weighed 12.7 g. If Li atoms are conserved, the percentage yield is : (Li = 7, Al = 27, H = 1, C = 12, O = 16).

(A) 25% (B) 75% (C) 100% (D) 15%

Ans. (C)

Sol. $Li\,AlH_4$ + t-butyl alcohol $\xrightarrow{\text{Ether}}$ $LiAlH\,C_{12}H_{27}O_3$ (M.W. = 254)

0.05 mole 12.7 gram

$$= \frac{12.7}{254} = 0.05 \text{ mole}$$

Li atom remain conserved so

No. of mole of $LiAlH_4$ = No. of mole of $LiAlHC_{12}H_{27}O_3$

So No. of mole of $LiAlHC_{12}H_{27}O_3$ = 0.05

$$\%\ \text{yield} = \frac{0.05}{0.05} \times 100 = 100\%$$

4.5 PERCENTAGE PURITY:

Ex.24 How much marble of 90.5 % purity would be required to prepare 10 litres of CO_2 at 1 atm ,0 ºCwhen the marble is acted upon by dilute HCl ?

Ans. 49.326 g

Sol. $CaCO_3 + 2HCl \longrightarrow CaCl_2 + H_2O + CO_2$

100 g 22.4litre

22.4 L of CO_2 at STP will be obtained from 100 g of $CaCO_3$

$\therefore$ 10 L of CO_2 will be obtained from pure $CaCO_3$ = $\frac{100}{22.4} \times 10 = 44.64$ g

$\therefore$ Impure marble required = $\frac{100}{90.5} \times 44.64 = 49.326$ g

4.6 SEQUENTIAL REACTIONS:

This reaction is defined as that reaction which proceeds from reactants to final products through one or more intermediate stages. The overall reaction is a result of several successive or consecutive steps.

Example: $A \rightarrow B \rightarrow C$

Ex.25 Minimum amount of Ag_2CO_3 (s) required to produce sufficient oxygen for the complete combustion of C_2H_2 which produces 11.2 L of CO_2 at 1 atm and 273K after combustion is: [Ag = 108]

$$Ag_2CO_3\,(s) \longrightarrow 2Ag\,(s) + CO_2\,(g) + 1/2\,O_2\,(g)$$

$$C_2H_2 + 5/2\ O_2 \longrightarrow 2CO_2 + H_2O$$

Ans. 345 g

Sol. $Ag_2CO_3\ (s) \longrightarrow 2Ag\ (s) + CO_2\ (g) + 1/2\ O_2\ (g)$

$C_2H_2 + 5/2\ O_2 \longrightarrow 2CO_2 + H_2O$

By Stoichiometry of reaction

Moles of CO_2 formed $= \frac{11.2}{22.4} = \frac{1}{2}$

Moles of O_2 required $= \frac{5}{4} \times \frac{1}{2} = \frac{5}{8}$

Moles of Ag_2CO_3 required $= 2 \times \frac{5}{8} = \frac{5}{4}$

Mass of Ag_2CO_3 required $= \frac{5}{4} \times 276 = 345$ g

Ex.26 NX is produced by the following step of reactions

$M + X_2 \longrightarrow MX_2$

$3MX_2 + X_2 \longrightarrow M_3X_8$

$M_3X_8 + N_2CO_3 \longrightarrow NX + CO_2 + M_3O_4$

How much M (metal) is consumed to produce 206 g of NX.

(Take at wt of M = 56, N=23, X = 80)

(A) 42 g (B) 56 g (C) 52g (D) 64 g

Ans. (A)

Sol. $M + X_2 \longrightarrow MX_2$

$MX_2 + X_2 \longrightarrow M_3X_8$

$M_3X_8 + Na_2CO_3 \longrightarrow NX + CO_2 + M_3O_4$

mole of NX $= \frac{206}{103} = 2$

POAC for X Atom :

No. of X atom in M_3X_8 = No. of X Atom in NX

8 [No. of mole of M_3X_8] = 1 [No. of mole of NX]

No. of mole of $M_3X_8 = \left[\frac{2}{8}\right] = \frac{1}{4}$ mole

Now POAC for M Atom

3 [No. of mole of M_3X_8] = 1 × [No. of Mole of M]

$\therefore$ $3 \times \frac{1}{4}$ = No. of mole of M

weight of M atom $= \frac{3}{4} \times 56 = 42$ gram

Ex.27 The following process has been used to obtain iodine from oil-field brines in California.

$$NaI + AgNO_3 \longrightarrow AgI + NaNO_3 \ ;$$

$$2AgI + Fe \longrightarrow FeI_2 + 2Ag$$

$$2FeI_2 + 3Cl_2 \longrightarrow 2FeCl_3 + 2I_2$$

How many grams of $AgNO_3$ are required in the first step for every 254 kg I_2 produced in the third step.

(A) 340 kg (B) 85 kg (C) 68 kg (D) 380 kg

Ans. (A)

Sol. Balanced equation :

$$NaI + AgNO_3 \longrightarrow AgI + NaNO_3 \quad (1)$$

$$2AgI + Fe \longrightarrow FeI_2 + 2Ag \quad (2)$$

$$2FeI_2 + 3Cl_2 \longrightarrow 2FeCl_3 + 2I_2 \quad (3)$$

From (3)

$$\frac{\text{mole of } I_2}{2} = \frac{\text{mole of } FeI_2}{2}$$

$$\frac{\text{mole of } FeI_2}{1} = \frac{\text{mole of } AgI}{2}$$

$$\frac{\text{mole of } AgI}{1} = \frac{\text{mole of } AgNO_3}{1}$$

$\therefore$ mole of I_2 = (mole of FeI_2)

$$= \left(\frac{\text{mole of } AgI}{2}\right) = \left(\frac{\text{mole of } AgNO_3}{2}\right)$$

$$\frac{254 \times 10^3}{254} = \frac{\text{mole of } AgNO_3}{2}$$

$$2 \times 10^3 = \text{mole of } AgNO_3 = \frac{\text{mass of } AgNO_3}{\text{molar mass of } AgNO_3}$$

mass of $AgNO_3 = 170 \times (2 \times 10^3)$ g $= 340 \times 10^3$ g = 340 kg.

4.7 PARALLEL REACTIONS:

The reactions in which a substance reacts or decomposes in more than one way are called parallel or side reactions.

Example: $A \longrightarrow B$

$A \longrightarrow C$

Ex.28 Find out moles of CO_2 & CO produced by combustion of 2 mol carbon with 1.25 O_2 leaving number residue:

Ans. CO_2 = 0.5 mol, CO_2 = 1.5 mol

Sol.

$$C + O2 \longrightarrow CO_2$$

x x x

$$C + \frac{1}{2} O_2 \longrightarrow CO$$

$$2-x \quad \frac{2-x}{2} \quad 2-x$$

$$x + 1 - \frac{x}{2} = 1.25$$

$$\frac{x}{2} = \frac{125}{100}$$

x = 0.5 mol, CO_2 = 0.5 mol, CO_2 = 1.5 mol

4.8 MIXTURE ANALYSIS:

The analysis of a chemical reaction is generally carried out in the form of mass of reacting species taking part in a given reaction **(gravimetric analysis)** or in terms of concentrations of reacting species taking part in a given reaction **(volumetric analysis).** In Gravimetric Analysis, we generally analyse reactions such as : decomposition of compounds under heat to produce a residue and a gas, or displacement reactions, action of acids on metals, or simple balanced chemical equations involving Weight (solid) – Volume (gas) relationships. In Volumetric Analysis, we generally analyse Neutralisation and Redox Titrations involving aqueous solutions in general.

(i) Except Li carbonates of all the alkali metals are thermally stable and does not decompose on heating. $Li_2CO_3 \xrightarrow{\Delta} Li_2O + CO_2$

$$M_2CO_3 \xrightarrow{\Delta} \text{No reaction}$$

(M = Na, K, Rb, Cs)

(ii) All the carbonates of alkaline earth metals are thermally unstable and decompose on heating as follow.

$$MCO_3 \xrightarrow{\Delta} MO + CO_2$$

(iii) Bicarbonates of both alkali metals and alkaline earth metals are decomposed at relatively low temperature as follow.

$$2MHCO_3 \xrightarrow{\Delta} M_2CO_3 + H_2O + CO_2$$

$$M(HCO_3)_2 \xrightarrow{\Delta} MCO_3 + CO_2 + H_2O$$

Ex.29 A sample of 3 g containing Na_2CO_3 and $NaHCO_3$ loses 0.248 g when heated to 300°C, the temperature at which $NaHCO_3$ decomposes to Na_2CO_3, CO_2 and H_2O. What is the percentage of Na_2CO_3 in the given mixture?

Ans. 77.48%

Sol. The loss in weight is due to removal of CO_2 and H_2O which escape out on heating.

wt. of Na_2CO_3 in the product = 3.00 – 0.248 = 2.752 g

Let wt. of Na_2CO_3 in the mixture be x g

$\therefore$ wt. of $NaHCO_3$ = (3.00 – x) g

Since Na_2CO_3 in the products contains x g of unchanged reactant Na_2CO_3 and rest produced from $NaHCO_3$.

The wt. of Na_2CO_3 produced by $NaHCO_3$ = (2.752 – x)g

$NaHCO_3 \longrightarrow Na_2CO_3 + (H_2O + CO_2)\uparrow$

(3.0 – x) (2.752 – x)

Applying POAC for Na atom

1 × moles of $NaHCO_3$ = 2 × moles of $Na_2CO_3 \Rightarrow \frac{(3-x)}{84} = 2x\frac{(2.752-x)}{106}$

$\therefore$ x = 2.3244 g

$\therefore$ % of Na_2CP_3 = $\frac{2.3244}{3} \times 100 = 77.48\%$

Ex.30 10 g of a sample of a mixture of $CaCl_2$ and NaCl is treated to precipitate all the calcium as $CaCO_3$. This Ca CO_3 is heated to convert all the Ca to CaO and the final mass of CaO is 1.62 g. The percent by mass of $CaCl_2$ in the original mixture is.

(A) 32.1 % (B) 16.2 % (C) 21.8 % (D) 11.0 %

Ans. (A)

Sol. $CaCl_2$ + NaCl = 10 g

Let weight of $CaCl_2$ = x g

$CaCl \rightarrow CaCO_3 \rightarrow CaO$

1 mol 1 mol 1 mol

$\frac{x}{111}$ mol $\frac{x}{111}$ mol $\frac{x}{111}$ mol

Mole of CaO = $\frac{1.62}{56}$

$\therefore \frac{x}{111} = \frac{1.62}{56}$

x = 3.21 g

% of $CaCl_2$ = $\frac{3.21}{10} \times 100 = 32.1$ %

5. DENSITY:

It is of two type.

1 . Absolute density 2 . Relative density

(a) For liquid and solids

$$\text{Absolute density} = \frac{\text{mass}}{\text{volume}}$$

$$\text{Relative density or specific gravity} = \frac{\text{density of the substance}}{\text{density of water at } 4^\circ C}$$

(b) For gasses:

Absolute density (mass / volume) = $\frac{PM}{RT}$

where P is pressure of gas, M = mol. wt. of gas, R is the gas constant, T is the temperature.

Relative density andVapour density:

Vapour density is defined as the density of the gas with respect to hydrogen gas at the same temperature and pressure.

Vapour density = $\frac{d_{gas}}{d_{H_2}} = \frac{PM_{gas}/RT}{PM_{H_2}/RT}$

V.D. $= \frac{M_{gas}}{M_{H_2}} = \frac{M_{gas}}{2} \Rightarrow \boxed{M_{gas} = 2V.D.}$

Ex.31 Find the relative density of SO_3 gas with respect to methane :

(A) 8 (B) 3.5 (C) 2.5 (D) 5

(A) 66.75 (B) 321 (C) 267 (D) 80.25

Ans. (A)

Sol. Element must be Al

Hence, volatile chloride will be $AlCl_3$ so V.D. = $\frac{M_{AlCl_3}}{2} = \frac{133.5}{2} = 66.75$

Ex.33 The density of water at 4°C is 1×10^3 kg m^{-3}. Assuming no empty space to be present between water molecules, the volume occupied by one molecule of water is approximately :

(A) 3×10^{-23} mL (B) 6×10^{-23} mL (C) 3×10^{-22} mL (D) 6×10^{-22} mL

Ans. (A)

Sol. 1×10^3 kg/m^3 = 1 g/mL. [Since, 1m^3 = 10^6 cm^3 = 10^6 mL].

= 1 gm/cc

6.022×10^{23} H_2O molecule weigh …18 g

1 H_2O molecule weigh .. $\frac{18}{6.022 \times 10^{23}}$ g = 3×10^{-23} g

$d = \frac{mass}{volume}$, So, volume = $\frac{3 \times 10^{-23}\ g}{1(g/mL)}$ = 3×10^{-23}mL.

6. AVERAGE/ MEAN ATOMIC MASS :

The weighted average of the isotopic masses of the element's naturally occuring isotopes.

Mathematically, average atomic mass of X (A_x) = $\dfrac{a_1x_1 + a_2x_2 + ... + a_nx_n}{100}$

Where :

a_1, a_2, a_3 .... atomic mass of isotopes.

and x_1, x_2, x_3 .... mole % of isotopes.

Ex.34 Naturally occurring chlorine is 75.53% Cl^{35} which has an atomic mass of 34.969 amu and 24.47% Cl^{37} which has a mass of 36.966 amu. Calculate the average atomic mass of chlorine -

(A) 35.5 amu (B) 36.5 amu (C) 71 amu (D) 72 amu

Sol. (A) Average atomic mass =

(% of I isotope × Its atoms mass)+(% II isotope × its atomic mass)/ 100

$= \dfrac{75.53 \times 34.969 + 24.47 \times 36.96}{100}$

= 35.5 amu.

6.1 AVERAGE MOLAR MASS OR AVERAGE GRAM MOLECULAR MASS:

The average molar mass of the different substance present in the container $= \dfrac{n_1M_1 + n_2M_2 + ...n_nM_n}{n_1 + n_2 + ...n_n}$

Where :

M_1, M_2, M_3 .... are molar masses.

n_1, n_2, n_3 .... moles of substances.

Average molecule wt. = $\dfrac{\Sigma n_iM_i}{\Sigma n_i}$ where n_i = no. of moles of compound, m_i = molecular mass of compound

Ex.35 The molar composition of polluted air is as follows :

Gas	mole percentage composition
Oxygen	16%
Nitrogen	80%
Carbon dioxide	03%
Sulphurdioxide	01%

What is the average molecular weight of the given polluted air ?

Ans. 29.48

Sol. $M_{avg} = \dfrac{16 \text{ x } 32 + 80 \text{ x } 28 + 44 \text{ x } 3 + 64 \text{ x } 1}{100} = \dfrac{512 + 2240 + 132 + 64}{100} = \dfrac{2948}{100} = 29.48$

6.2 DEGREE OF DISSOCIATION (α):

Degree of dissociation represents the fraction of one mole dissociated into the products. (Defined for one mole of substance)

So, α = no. of moles dissociated / initial no. of moles taken

= fraction of moles dissociated out of 1 mole.

Note : % dissociation = α x 100

Suppose 5 moles of PCl_5 is taken and if 2 moles of PCl_5 dissociated then $\alpha = \frac{2}{5} = 0.4$

6.3 RELATIONSHIP BETWEEN AVERAGE MOLAR MASS& DEGREE OF DISSOCIATION (α):

Let a gas A_n dissociates to give n moles of A as follows-

$$
\begin{array}{llll}
 & A_n\,(g) \rightleftharpoons & n\,A\,(g) & \\
t = 0 & a & 0 & \\
t = t_{eq} & a - x & nx & \alpha = \frac{x}{a} \Rightarrow \quad x = a\alpha. \\
 & a - a\,\alpha = a(1-\alpha) & n\,a\,\alpha &
\end{array}
$$

Total no. of moles = $a - a\,\alpha + n\,a\,\alpha$

$= [1 + (n - 1)\,\alpha]\,a$

Average molecular weight of mixture(g)= $\frac{\text{molecular weight of } A_n(g)}{\text{total no. of moles at equilibrium}}$

$$= \frac{a.M_{th}}{a(1+(n-1)\alpha)}$$

$$M_{avg} = \frac{M_{th}}{[1+(n-1)\alpha]}$$

where M_{th} = theoritical molecular weight (n = atomicity)

$$M_{mixture} = \frac{M_{A_n}}{[1+(n-1)\alpha]}, \quad M_{A_n} = \text{Molar mass of gas } A_n$$

Vapour density (V.D). : Density of the gas divided by density of hydrogen under same temperature & pressure is called vapour density.

D = vapour density without dissociation = $\frac{M_{A_n}}{2}$

d = vapour density of mixture = averagevapour density

$$\frac{D}{d} = 1 + (n - 1)\,\alpha$$

$$\alpha = \frac{D-d}{(n-1)\times d} = \frac{M_T - M_o}{(n-1)M_0}$$

Ex.36 NH_3 decomposes into N_2 & H_2. If average molar mass of reaction mixture is 10 then, find α ?

Ans. 0.7

Sol.

$$NH_3 \longrightarrow \frac{1}{2}N_2 + \frac{3}{2}H_2$$

$$\begin{array}{llll} n_1 & 1 & 0 & 0 \\ & 1-\alpha & \frac{\alpha}{2} & \frac{3\alpha}{2} \end{array}$$

$$10 = \frac{17}{1-\alpha+\frac{\alpha}{2}+\frac{3\alpha}{2}}$$

$$10 = \frac{17}{1+\alpha}$$

$1 + \alpha = 1.7$

$\alpha = 0.7$

7. PERCENTAGE COMPOSITION AND MOLECULAR FORMULA :

Here we are going to find out the percentage of each element in the compound by knowing the molecular formula of compound.

We known that according to law of definite proportion any sample of a pure compound always possess constant ratio with their combining elements.

- **Example:**

Every molecule of ammonia always has formula NH_3 irrespective of method of preparation or sources. i.e. 1 mole of ammonia always contains 1 mol of N and 3 mole of H. In other wards 17 g of NH_3 always contains 14 g of N and 3 g of H. Now find out % of each element in the compound.

Mass % of N in NH_3 = $\dfrac{\text{Mass of N in 1 mol } NH_3}{\text{Mass of 1 mol of } NH_3}$ 100 = $\dfrac{14g}{17}$ 100 = 82.35 %

Mass % of H in NH_3 = $\dfrac{\text{Mass of H in 1 mol } NH_3}{\text{Mass of 1 mol of } NH_3}$ 100 = $\dfrac{3}{17}$ 100 = 17.65%

7.1. EMPIRICAL AND MOLECULAR FORMULA:

We have just seen that knowing the molecular formula of the compound we can calculate percentage composition of the elements. Conversely if we know the percentage composition of the elements initially, we can calculate the relative number of atoms of each element in the molecules of the compound. This gives as the empirical formula of the compound. Further if the molecular mass is known then the molecular formula can be easily determined.

Thus, the empirical formula of a compound is a chemical formula showing the relative number of atoms in the simplest ratio, the molecular formula gives the actual number of atoms of eachelement in a molecule.

Empirical formula: An empirical formula represents the simple whole number ratio of various atoms present in a compound,

Molecular formula: whereas, the molecular formula shows the exact number of different types of atoms present in a molecule of a compound

The molecular formula is generally an integral multiple of the empirical formula.

That is : $\boxed{\text{molecular formula} = \text{empirical formula} \times n}$

$$\text{where } n = \frac{\text{molecular formula mass}}{\text{emprirical formula mass}}$$

Ex.37 An organic substance containing carbon, hydrogen and oxygen gave the following percentage composition.

C = 40.687 % ; H = 5.085 % and O = 54.228 %

The molecular weight of the compound is 118. Calculate the molecular formula of the compound.

Ans. $C_4H_6O_4$

Sol. **Step -1**

To calculate the empirical formula of the compound.

Element	Symbol	Percentage of element	At. mass of element	Relative no. of atoms = $\frac{\text{Percentage}}{\text{At.mass}}$	Simplest Atomic ratio	Simplest whole no. atomic ratio
Carbon	C	40.687	12	$\frac{40.687}{12} = 3.390$	$\frac{3.390}{3.389} = 1$	2
Hydrogen	H	5.085	1	$\frac{5.085}{1} = 5.035$	$\frac{5.085}{3.389} = 1.5$	3
Oxygen	O	54.228	16	$\frac{54.228}{16} = 3.389$	$\frac{3.389}{3.389} = 1$	2

- **Step - 2**

  To calculate the empirical formula mass.

  The empirical formula of the compound is $C_2H_3O_2$.

  $\therefore$ Empirical formula mass

  $= (2 \times 12) + (3 \times 1) + (2 \times 16) = 59.$

- **Step - 3**

  To calculate the value of 'n'

  $$n = \frac{\text{molecular mass}}{\text{Empirical formula nass}} = \frac{118}{59} = 2$$

- **Step - 4**

  To calculate the molecular formula of the salt

  Molecular formula $= n \times (\text{Empirical formula})$

  $= 2 \times C_2H_3O_2 = C_4H_6O_4$

  Thus the molecular formula is $C_4H_6O_4$.

Ex.38 Chlorophyll the green colouring material of plants contains 3.68 % of magnesium by mass. Calculate the number of magnesium atom in 5.00 g of the complex.

Sol. Mass of magnesium in5.0 g of complex = $\frac{3.68}{100}$ 5.00 = 0.184 g

Atomic mass of magnesium = 24

24 g of magnesium contain = 6.023×10^{23} atoms

0.184 g of magnesium would contain = $\frac{6.023 \times 10^{23}}{24}$ 0.184 = 4.617 × 1021 atom

Therefore, 5.00 g of the given complex would contain 4.617×10^{21} atoms of magnesium.

Ex.39 A sample of $CaCO_3$ has Ca = 40%, C = 12% and O = 48% by mass. If the law of constant proportions is true, then the mass of Ca in 5 g of $CaCO_3$ obtained from another source will be:

(A) 0.2 g (B) 2 g (C) 0.6 g (D) Cannot be determined

Ans. (B)

Sol. Mass of Ca = $5 \times \frac{40}{100}$ = 2g.

8. EXPERIMENTAL METHODS TO DETERMINE ATOMIC & MOLECULAR MASSES

8.1 For determination of atomic mass :

(*a*) Dulong's & Pettit' slaw :

In case of metals, it is observed that product of atomic weight and specific heat capacity is constant.

The equation connecting the two parameters was given by Dulong's and Petit's Law.

Atomic weight of metal × specific heat capacity (cal/gm°C) = 6.4.

In should be remembered that this law is an empirical observation and this gives an approximate value of atomic weight. Also this law can be applied only to metals at high temperature conditions only.

8.2 Experimental methods for molecular mass determination.

(a) Victor Meyer's Method

(b) Silver Salt Method

(c) Chloroplatinate Salt Method

(a) Victor Meyer's Method: (Applicable for volatile substance)

A known mass of the volatile substance taken in the Hoffmann's bottle and is vapourised by throwing the Hoffmann's bottle into the Vector Meyer's tube. The vapour displace an equal volume of the moist air. Which vapours is measured at the room temperature and atmospheric pressure. The barometric pressure and the room temperature is recorded. Following diagram gives the experimental set-up for the Victor-Meyer's process.

Calculation involved

Let the mass of the substance taken by = Wg

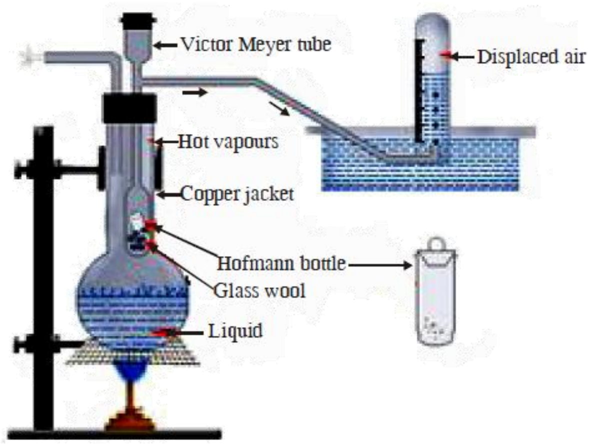
Volume of moist vapours collected = Vcm^3

Room temperature = TK

Barometric pressure = P mm
Aqueous tension at TK = p mm
Pressure of dry vapour = (P – p) mm
Calculation of molecular mass (M)

$$\frac{(P-p)}{760}\times\frac{V}{1000} = \frac{w}{M}\times RT$$

$$\Rightarrow \qquad M = \frac{w\times RT\times 760\times 1000}{(P-p)\times V}$$



(b) Silver salt Method: (A used for organic acids)

A known mass of the acid is dissolved in water followed by the subsequent addition of silver nitrate solution till the precipitation of silver salt is complete. The precipitate is separated, dried, weighed

$$\text{Organic acid} \xrightarrow{AgNO_3} \text{Silver salt} \xrightarrow{\text{Ignite}} Ag$$

and ignited till decomposition is complete. The residue of pure silver left behind is weighed.
Calculations involved
Let the mass of the silver salt formed = W g
The mass of Ag formed = x g
Let us understand to calculations by considering the monobasic acid MX.

$$\underset{\text{Organic acid}}{HA} \xrightarrow{AgNO_3} \underset{\text{Silver salt(Wg)}}{AgA} \xrightarrow{\text{Tgnite}} \underset{\text{Silver(xg)}}{Ag}$$

Mass of the salt that gives x gm of Ag = W g

Mass of the salt gives 108g (1g-atom) of Ag = $\frac{108W}{x}$ g

Molar mass of salt = $\frac{108W}{x}$ g

Molar mass of acid = (Molar mass of salt) – (Atomic mass of Ag) + (Atomic mass of H)

$$= \frac{108W}{x} - 108 + 1 = \left(\frac{108W}{x} - 107\right) g\,mol^{-1}$$

For polybasic acid of the type H_nX (n is basicity)

$$\underset{\text{Organic acid}}{H_nA} \xrightarrow{AgNO_3} \underset{\text{Silver salt (Wg)}}{Ag_nA} \xrightarrow{\text{Tgnite}} \underset{\text{Silver (xg)}}{nAg}$$

Mass of the silver that gives x g of Ag = W g

Mass of the silver that gives (108n g) of Ag = $\frac{108nW}{x}$ g

Molar mass of salt = $\frac{108 \times nW}{x}$ g

Molar mass of acid = (molar mass of salt) = $\frac{108 \times nW}{x} - n \times 108 - n \times 1$

$= n\left(\frac{108W}{x} - 107\right) g\,mol^{-1}$

(c) Platinic chloride Method : (Applicable for finding the molecular masses of organic bases).

A known mass of organic base is allowed to react with chloroplatinic acid (H_2PtCl_6) in conc. HCl to form insoluble platinic chloride. The precipitate of platinic chloride is separated, dried, weighed and subsequently ignited till decomposition is complete. The residue left is platinum which is again weighed. The molecular mass is then calculated by knowing the mass of the platinic chloride salt and that of platinum left.

If B represents the molecule of monoacidic organic base, then the formula of platinic chloride salt is

$B_2H_2PtCl_6$.

$$\underset{\text{Organic base}}{B} \xrightarrow[\text{conc. HCl}]{H_2PtCl_6} \underset{\text{Platinic chloride salt (Wg)}}{B_2H_2PtCl_6} \xrightarrow{\text{lgnite}} \underset{(xg)}{Pt}$$

Let the mass of platinic chloride salt = W g, The mass of the platinum residue left = x g

It may be noted that salt formed with diacidic base would be $B_2\ (H_2PtCl_6)_2$

With triacidic base it would be $B_2\ (H_2PtCl_6)_3$ and with polyacidic base would be $B_2(H_2PtCl_6)_n$.

Mass of salt which gives 195 g (1 g–atom) of Pt $\frac{W \times 195}{x}$ g

Molar mass of salt = $\frac{W \times 195}{x} g\,mol^{-1}$

Now from the formula $B_2(H_2PtCl_6)$

Molar mass of salt = (2 × molar mass of base) + (Molar mass of H_2PtCl_6)

Molar mass of base = $\frac{1}{2}$ (molar mass of salt – Molar mass of H_2PtCl_6)

$$= \frac{1}{2}\left(\frac{W \times 195 \times n}{x} - n \times 410\right) = \frac{n}{2}\left(\frac{w \times 195}{x} - 410\right) g\,mol^{-1}$$
