

# SURVEYING

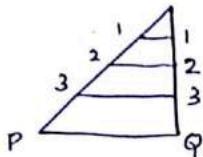

Plane surveying	Geodetic surveying	In Geodetic surveying →
Earth surface not taken into account	taken into account Surface curvature of earth taken	Topic → spherical Triangle :
For small area ( $< 195.5 \text{ km}^2$ )	for Larger area ( $> 195.5 \text{ km}^2$ )	 <p>1- any angle <math>&lt; 180^\circ</math> 2 right angle</p>
	$18.5 \text{ km} \rightarrow 1.52 \text{ cm}$ $19.5 \text{ km}^2 \rightarrow 18 \text{ cm}^2$	$180^\circ < A + B + C < 540^\circ$ $\pi \text{ angle sum}$ $3\pi$
Less accurate	more accurate	<p>3- sum of any 2 side <math>&gt;</math> Third side  <math>a+b&gt;c</math>  <math>b+c&gt;a</math>  <math>a+c&gt;b</math></p>
Line joining 2 points in this is line	arc	<p>4- if sum of any 2 side <math>= \pi</math> then sum of angle opposite them is also <math>\pi</math> (<math>180^\circ</math>)  if <math>a+b=\pi</math> then <math>A+B=2\times 90=180=\pi</math></p>
uses:- on Large scale like dam, bridge, highway	uses:- in establishing control point for plane Survey (done by national survey of India)	<p>5- The smaller angle is opposite the smaller side.</p>
classification of survey based on		<p>6- sum of 3 sides of Spherical Triangle is always Less than circumference of Great circle.</p>
nature of field survey	object of survey	principle of surveying :
1- Land Survey (Ex. Cadastral Survey, City Survey)	1- Engineering Survey	① Whole to part
2- marine or hydrographic survey	2- Milling "	• localize the error & prevent their accumulation
3- Astronomical Survey	3- Geological "	② Locate a point by at least 2 measurements
4- Topographical Survey	4- Archaeological "	
5- Hydrographic Survey	5- Mine "	$\text{Scale} = \frac{\text{Map distance}}{\text{Ground distance}}$ max. error on drawing = 0.25 mm
6- Astronomical Survey	6- Traverse "	<p>• High Representative fraction <math>\rightarrow</math> larger scale (RF)</p>
7- Geodetic Survey	7- Geodesy "	$\text{Shrinkage factor (SF)} = \frac{\text{Shrunk length}}{\text{Original Length}}$
8- Remote Sensing Survey	8- Remote Sensing "	$\text{Shrunk scale} = \text{Original scale} \times SF$
9- Geophysical Survey	9- Geophysical "	$\text{Correct Length} \times RF_{\text{correct scale}} = \text{Measure length} \times RF_{\text{wrong scale}}$ $\text{Correct area} \times (RF_{\text{correct scale}})^2 = \text{Measure area} \times (RF_{\text{wrong scale}})^2$
10- Geodetic Survey	10- Geodetic "	$\text{Correct distance on map (in terms of original scale)} = \frac{\text{Measure dist. on map}}{SF}$ $\text{Area} = \frac{\text{Measure area}}{(SF)^2}$ $\text{Volume} = \frac{\text{Measure volume}}{(SF)^3}$

## Types of scales :

→ 3 dimension (meter, centi, decimal)

① Diagonal scale :- used to represent 3 units  
(main unit, its subunit, subdivision of subunit)

- Based on similarity of Triangle.
- indicate the distances in unit and its immediate 2 subdivisions.

$$1-1 \text{ represent } \frac{1}{4} PQ$$

$$2-2 \quad " \quad \frac{2}{4} PQ$$

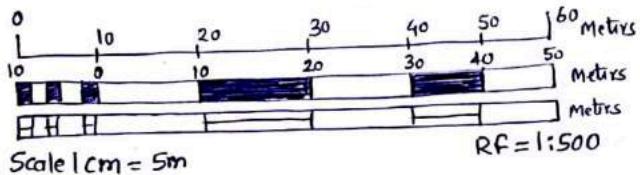

$$3-3 \quad " \quad \frac{3}{4} PQ$$

② Graphical scale :- is a line subdivided into place distance corresponding to convenient unit of length.

Exmp

- Always drawn on all Survey maps

- Graphical scale not affected due to shrinkage of map. { if a graphical scale is drawn on map and in case shrinkage of sheet / paper occurs then graphical scale also shrinks proportionally & therefore ratio is unaffected.

③ Vernier scale :- Used when diagonal scale is inconvenient to use due to lack of space.

- can read upto 2 decimal place

- more precise than plain scale

- vernier scale has 2 parts

Used to represent 2 consecutive units like meter & decimetre feet & inch

main scale  
is plain &  
uniformly  
divided

Vernier scale

It is an auxiliary scale whose length is either more or less by fixed amount compared to main scale division.

① Direct vernier

$$(n-1)S = nv$$

$$L \cdot C = S/n$$

• reading increases in a direction to that of the mainscale.

Ex. 9 division of main scale

= 10 division of vernier

② Retrograde vernier

$$(n+1)S = nv$$

$$L \cdot C = S/n$$

- reading increases in a direction opposite to that of main scale

③ Extended vernier

$$(2n-1)S = nv$$

$$L \cdot C = 2S - v$$

if may happen that divisions on the main scale are very and it would then be difficult, if the vernier were of normal length, to judge the exact graduations where coincidence occurs in this case it is used.

④ Double vernier

In measuring Angles

(vertical or horizontal)  
vernier may be moved in either direction on fixed main scale.

for such measurement double vernier used in which -  
Graduations are in both directions

$$\text{EDMI} = [(a \text{ mm}) + b(ppm)]$$

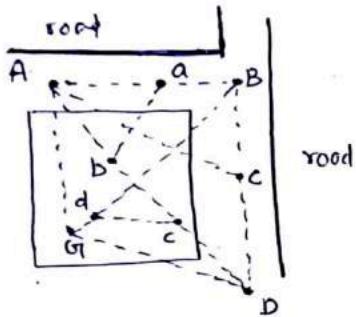

↓  
constant instrument error

Independent of Length measured

Varies in Proportion to the distance being measured

chaining: It is a measurement of horizontal distance either by chain or tape.

- used for area of small extent on open ground having few simple details
- not good for large areas having more details
- plans are required on a large scale because large scale consist of few details.

#### ① main station (A, B, C, D)

- command the boundary of survey
- where 2 sides of triangle meets.

#### ② Tie station / subsidiary station : (a, b, c, d)

Station on line joining main station.

#### ③ main survey line : (AB, BC, CD, DA, AD)

line joining main station

#### ④ Tie line / subsidiary line / Auxiliary line (ab, cd)

line joining tie station. provided to locate the interior detail which are far away from main survey line.

#### ⑤ Baseline : longest survey line on a fairly straight passing through centre of area

#### ⑥ check line / profile line : to check accuracy of work

#### ⑦ offset : lateral measurement from chain line (may be perpendicular or oblique)

Ravenue chain	Gunter's chain	Engineering chain
33 feet	66 feet	100 feet
16 link	100 link	100 link

metric chain

$20 \pm 5\text{mm}$

$20\text{metre chain}$   
 $(20 \times 5 = 100\text{link})$

$30 \pm 8\text{mm}$

$30\text{metre chain}$   
 $(30 \times 5 = 150\text{link})$

$1\text{mile} = 80 \times \text{Gunter chain}$

$1\text{acre} = 10 \times (\text{Gunter chain})^2$

note: Survey chain dist b/w 2 brassing = 20cm

note: Surveying chain accuracy not good As  
Steel tape / Steel Band

invar tape : Ni (36%) + Steel (64%)

• highly precise •  $\alpha \downarrow$  (very low)  $\rightarrow$  Less affected due to temp.

• width 6mm Length 80, 50, 100 meters.

accuracy of tape : Invar > steel > metallic > Linen

Accessories for chaining :

1- Pegs  $\rightarrow$  to mark point on ground.

2- Arrow  $\rightarrow$  पर जाए लंबाई नापने के तो जहाँ tape length रखते होते कहाँ Arrow लगाते

3- Ranging rod  $\rightarrow$  to locate intermediate points or to locate a no. of points on long survey line

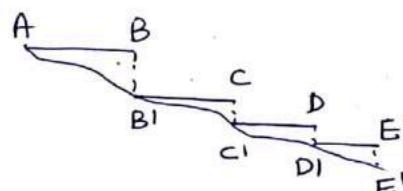

note: कई लंगीज dist. नापने के लिये ranging rod use कर सकते (20x3m long) (30mm dia)

4- offset rods  $\rightarrow$  to align offset line and to re-measure short offset.

• additional hook is provided on top to pull or push a rod.

chaining in sloping ground :

- 1- direct method / Stepping method / Breaking the chain method

- 2- Indirect method / re-measurement along slope / hypotenusal method

## Tape correction

① correction due to Standardization  
 $\begin{array}{c} (+) \\ (-) \end{array}$

$$\text{साथी} \times \text{साथी} = \text{गलत} \times \text{गलत}$$

② correction due to temp.  
 $\begin{array}{c} (+) \\ (-) \end{array}$

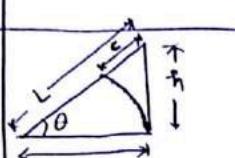

$$L \alpha (T_m - T_o) \quad \begin{array}{l} \oplus T_m > T_o \\ \ominus T_m < T_o \end{array}$$

$T_m \rightarrow$  measurement  
करते समय temp.  
 $T_o \rightarrow$  std. की temp.

③ correction due to pull  
 $\begin{array}{c} (+) \\ (-) \end{array}$

$$\frac{(P_m - P_o)L}{AE} \quad \begin{array}{l} \oplus P_m > P_o \\ \ominus P_m < P_o \end{array}$$

④ correction due to slope  
always  $\rightarrow$ ve

$$C = \frac{-h^2}{2L} = -(L - L \cos \theta)$$

Ex:  $L = 100 \text{ link} = 30 \text{ m}$   
 $\tan \theta = \frac{1}{n} \therefore \cos \theta = \frac{n}{\sqrt{1+n^2}}$

$$C = -(L - L \cos \theta) \\ = L \left[ \frac{n}{\sqrt{1+n^2}} - 1 \right]$$

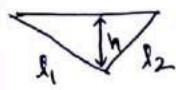

$$C = L \left[ \left( \frac{1+n^2}{n^2} \right)^{\frac{1}{2}} - 1 \right] = L \left[ \left( 1 + \frac{1}{n^2} \right)^{\frac{1}{2}} - 1 \right]$$

$$C = L \left[ 1 - \frac{1}{2} \left( \frac{1}{n^2} \right) + \dots - 1 \right]$$

$$C = -\frac{L}{2n^2}$$

$$\text{or } C = \frac{h^2}{2l} + \frac{h^4}{8l^3}$$

⑤ correction due to wrong alignment  
always  $\leftarrow$ ve

$$C = -\left( \frac{h^2}{2l_1} + \frac{h^2}{2l_2} \right)$$

⑥ correction due to sag  
always  $\leftarrow$ ve

$$C = -\frac{w^2 l^3}{24 P_m^2} \quad w \rightarrow \text{N/m}$$

normal tension :- when

$$C_{\text{pull}} = P_{\text{sag}}$$

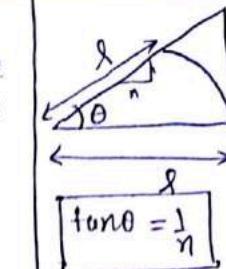

$$\frac{(P_m - P_o)L}{AE} = \frac{w^2 L^3}{24 P_m^2}$$

⑦ correction due to msl (mean sea level)  
always  $\leftarrow$ ve

$$C = -\frac{Lh}{R}$$

⑧ Hypotenuse Allowance

( $\theta$ )

$$C = l(\sec \theta - 1)$$

error in chaining :

① Compensating error  
(Random error)

- liable to occur in both the direction and tend to compensate

• Compensating error  $\propto \sqrt{\text{length of line}}$

- These are caused by incorrect holding & marking of arrow, incorrect plumbing at slopes
- They don't affect much result

- They can not be corrected

② Cumulative error

- liable to occur in same direction and tend to accumulate

Ex. error due to sag, slope etc

Cumulative error  $\propto$  length of line

- They can be corrected

chain adjustment (con Tensioning)

if chain found too short

if chain found too long.

1- Straightening bent links

2- flattening the circular rings

3- Replacing circular rings by bigger rings

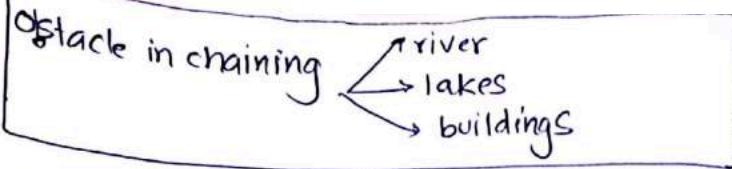

4- Insert additional ring

1- replace the wornout rings

2- closing the opened joint of rings

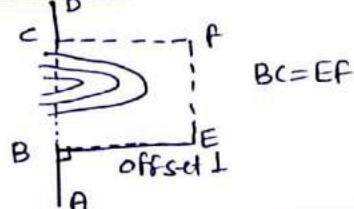

3- reshaping the elongated links

4- remove one or more circular rings

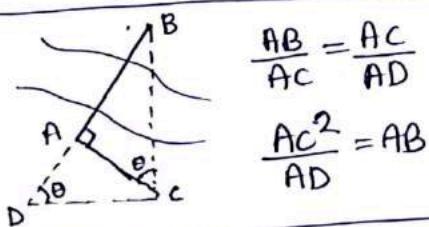

Prolongation of chain line across an obstruction in chain surveying :-

(1) Drawing Perpendicular with a chain

(2) making Angular measurement

Ranging :- process of establishing intermediate point

(1) Direct ranging

• where end station visible.

(a) ranging by eye

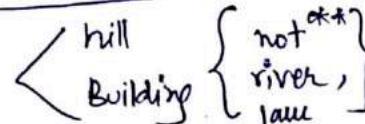

(b) ranging by line ranger

(2) Indirect ranging or reciprocal ranging

when end station not visible due to rising ground b/w them or due to long distance b/w end stations

note:- random line method of Ranging :-  
• [chain used to erect a  $\perp$  taking 3 sides of  $\Delta$  in ratio of 3:4:5]

Obstacle in ranging :-

Right Angle measurement :-

(1) crossstaff

(i) open cross staff

90°

(ii) french cross staff  
(Hollow octagonal Box)

45°/90°/135°

accuracy :- open cross staff better

(ii) optical square

Principle → double Reflection

• if angle b/w mirror is 45° then reflected ray is 90 degrees to incident ray

(iii) prism square

Principle same as optical square  
→ prism used.

Limiting Length of offset :- depends on :-

1- Degree of accuracy desired.

2- method of setting out perpendiculars

3- Nature of ground

4- Scale of Plotting

note:- max. allowable error length on drawing = 0.25 mm

Combined error in Length & direction :-

1 cm = S meter

$$l = \frac{1}{\sin \theta} \sqrt{\left(\frac{S}{40}\right)^2 - x^2}$$

error in length

if error in direction only, :- ( $x=0$ )

$$l = \frac{1}{\sin \theta} \sqrt{\left(\frac{S}{40}\right)^2 - 0^2}$$

Chain Surveying	Traverse Surveying
① Only linear measurement ∴ relatively easier	① Both linear & angular measurement.
② Framework consists of Triangles	② Framework consists of series of connected lines open or closed polygons
③ Check lines are rep. to check the accuracy of work	③ Method of Adjustment is used to check accuracy
④ Use → where area is small, ground flat & accuracy required is low	④ Use → large area, when accuracy required better

Traversing done by

- ① compass Traverse
- ② Plane Table "
- ③ Stadia "
- ④ Theodolite "

magnetic compass is req. to determine angle of traverse & side measured by chain/tape

meridian → fix line of reference.

{ I - True meridian II - magnetic meridian III - Grid meridian IV - Arbitrary meridian }

True meridian

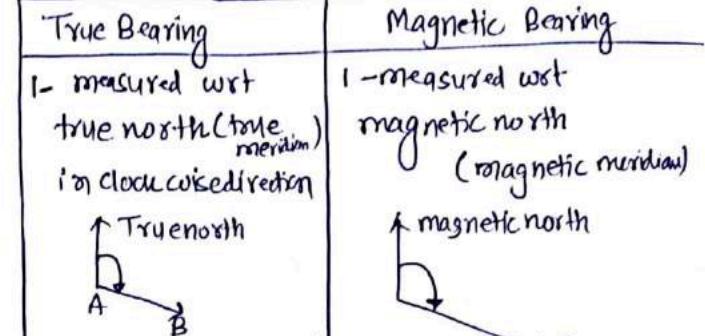

- True North-South direction at a place
- determined by Astronomical observation of sun or stars
- True meridians though various stations are not parallel. But, converge at poles. However for small survey, we assume parallel.
- at a point fixed always

magnetic meridian

- direction indicated by a freely suspended, balanced magnetic needle at that point.
- This magnetic needle should not be affected other than that of earth.
- At point varies with time (not fixed)

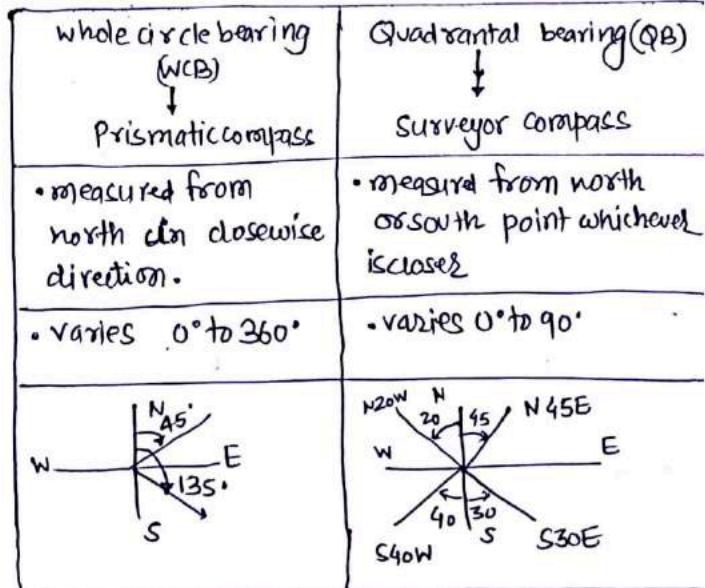

Bearing → Horizontal angle of line wrt reference line (meridian)

Azimuth → Bearing of a point in reference to the (True bearing) horizontal true north

(horizontal angle b/w True meridian line)

2 - does not change with time as True meridian at a point is fixed	2 - It changes with time as magnetic poles are not fixed in position
3 - It is determined by Astronomical observation	3 - determined by Prismatic compass or Surveyor's compass (QB)

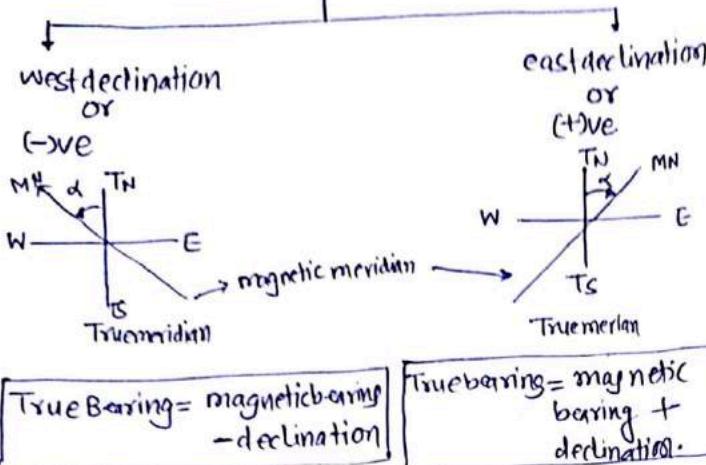

Fore bearing (FB) :- Bearing of line in the direction of progress.

Back bearing :- opposite direction of progress.

$$d = FB \quad A \quad B = BB \quad BB = fB \pm 180^\circ$$

(+) when  $fB < 180^\circ$   
(-) when  $fB > 180^\circ$

Magnetic Declination :- Horizontal angle b/w True meridian & magnetic-meridian.

Variation of Magnetic Declination :

I Secular variation	occurs continuously over a long period of time (like 150 years)
II Annual variation	(due to rotation of earth about sun) • changing declination at a place over a <u>period of 1 year</u> .
III Diurnal variation	(due to rotation of earth about own axis) • changing declination over a 24 hr at a place. Ex: Pole > equator Summer > winter day > night } comparison of change in declination.
IV Irregular variation	due to magnetic disturbances.

Local Attraction :- Attraction of magnetic-needle to local magnetic field (other than earth's magnetic field)

• caused by iron pipes, iron fence, railway line etc.

How to detect :-

① diff. b/w FB & BB  $\neq 180^\circ$

② error in observation of either FB, BB or both.

③ presence of local attraction at either 1 end or both ends

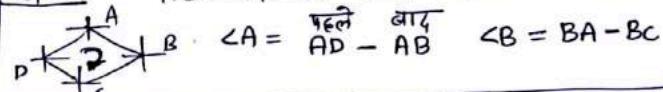

Dip :- angle made by line of magnetic force with earth surface.

- magnetic needle  $\rightarrow$  align with magnetic force
- In horizontal @ Equator dip = 0 }
- Vertical @ Pole dip =  $90^\circ$  } ( $0-90^\circ$ )

- 1- lines of equal annual change (magnetic Decl.)  $\Rightarrow$  Isoprs
- 2- Isogonic  $\rightarrow$  same magnetic Declination  
Agonic  $\rightarrow$  zero
- 3- Isoclinic  $\rightarrow$  same dip
- 4- Actinic  $\rightarrow$  zero dip

Prismatic compass (WCB)	Surveyor compass (QB)
magnetic needle	Broad needle
Graduated ring	 N 180° E 270° S 90° W 0°
reading system	with the help of prism provided at eye vane
tripod	instrument can be held in hand while making observations
vanes	eye vanes consists of a metal vane with a large slit
	eye vane consists of small vane with small slit

Type-1 :-  $|FB - BB| = 180^\circ \Rightarrow$  solve by interior angle

Type-2 :-  $|FB - BB| \neq 180^\circ \Rightarrow$  find interior angle  $\angle A$ , add suppose  $= (536^\circ) \angle A = 540^\circ$

$\therefore$  correction needed per angle  $= +4/5 = 0^\circ 48' 0''$

$\therefore$  new corrected angle  $= \angle A, \angle B$

assume AB as correct  $\therefore BB - FB = 180^\circ$

$\therefore \angle A = AE - AB$  find  $AE = ?$

motu :- ① Difference b/w FB & BB for any station  $\Rightarrow$  Interior Angle

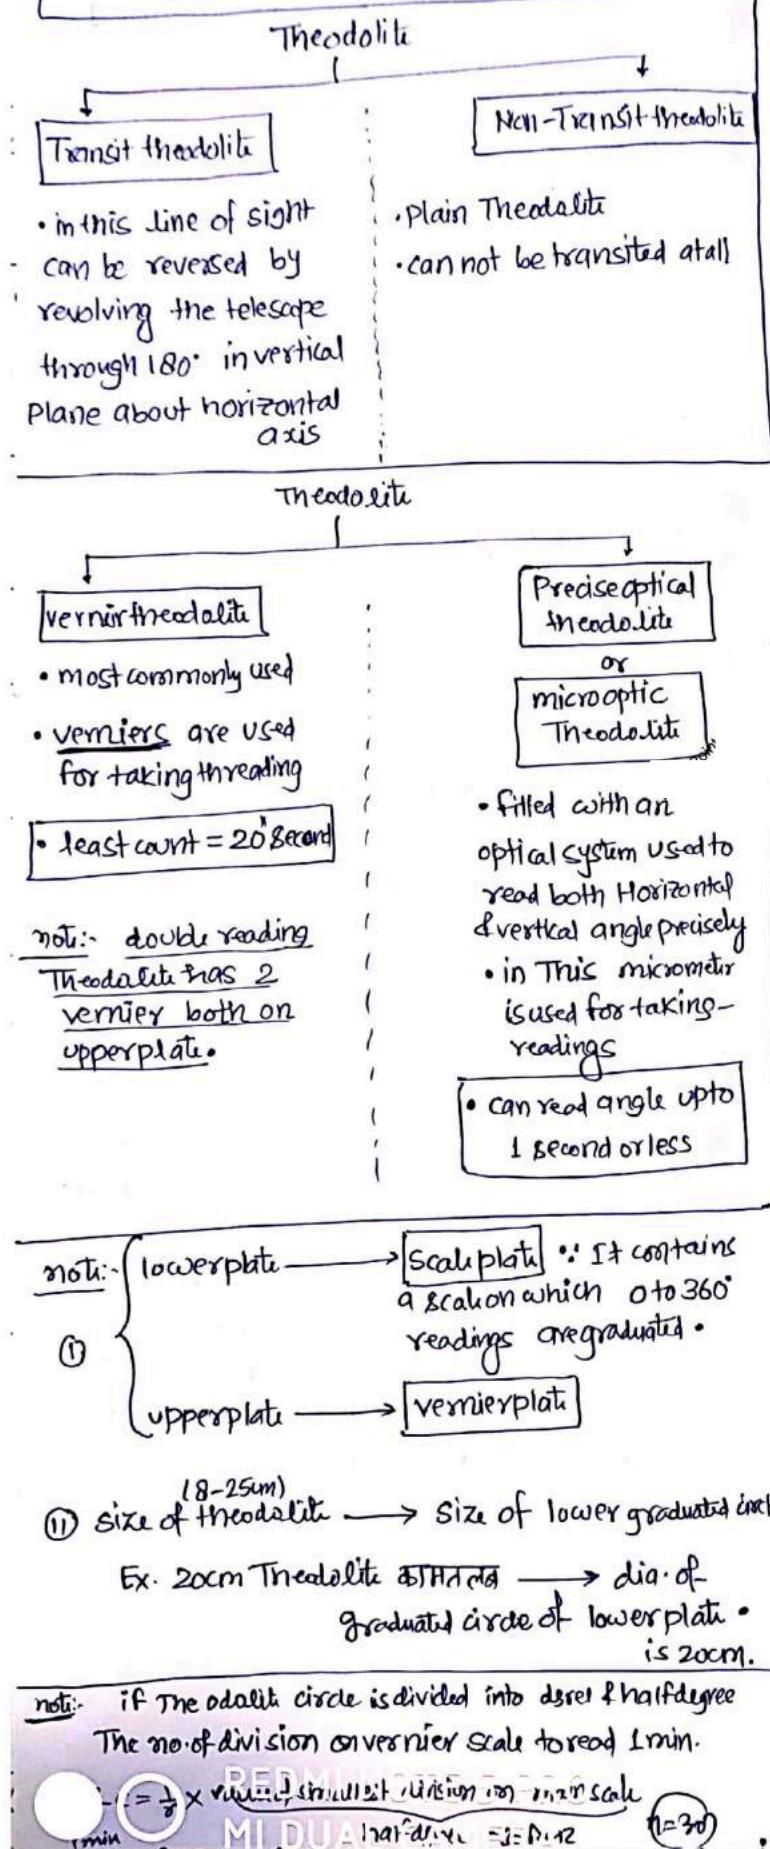

② included Angle = FB of next line - BB of previous line

③ if traverse clockwise  $\Rightarrow$  included Angle will be exterior Angle

④ If anti-clockwise  $\Rightarrow$  Interior Angle.

Theodolite use :-

- (i) to measure horizontal & vertical angle precisely.
- (ii) to measure horizontal & vertical distance indirectly.
- (iii) ranging.

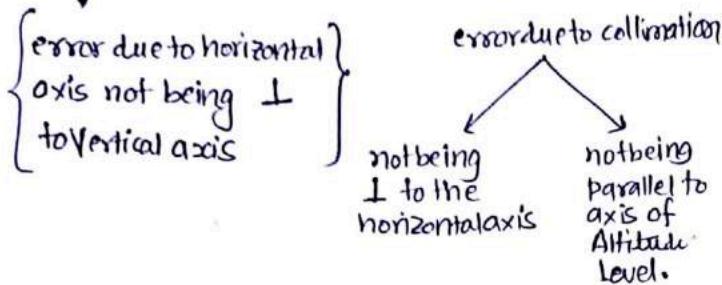

Basic Definitions:

- 1- centering :- setting up station exactly over station.
  - done by plumb bob.
- 2- Horizontal axis / Tranverse axis / Trunnion axis : axis about which Telescope can be rotated in vertical plane
- 3- Vertical axis / Azimuth axis  $\rightarrow$  @ Horizontal plane
- 4- Line of sight / Line of collimation :- Imaginary line passing through the intersection of crosshair of diaphragm and the optical centre of objective
  - when light comes in horizontal plane it is called line of collimation.
- 5- axis of level tube :- when bubble in centre then axis of Level tube is horizontal.
- 6- face right :- vertical circle of theodolite at right hand side of observer
- 7- face left :- at left
- notes:- collimation error can be eliminated by taking mean of both face reading.  
error =  $\frac{\text{Difference b/w faceright \& left observation}}{2}$
- 8- Telescope normal :- face left + bubble is up.
- 9- Telescope inverted  $\rightarrow$  face right + bubble is down.
- 10- Transit / plunging / Reversing :- about horizontal axis, rotate telescope by  $180^\circ$  in vertical plane (exactly opposite direction)
- 11- Swinging of Telescope :- about vertical axis, Telescope rotated in horizontal plane.
  - { sight swing  $\rightarrow$  clockwise rotation}
  - { left "  $\rightarrow$  anticlockwise " }
- 12- double sighting :- process of measure horizontal or vertical angle twice, one with telescope in normal condition, another with telescope in inverted condition.

13- changing face :- bringing the telescope from face left to face right or vice versa.

done by plunging + swinging by  $180^\circ$   
(Reversing)

error elimination by changing face

14- lining in :- process of establishing intermediate points with help of Theodolite on a given straight line whose ends are invisible.

15- Balancing In → ② whose ends are not invisible

note:- The tangential & rev. → used for minor adjustment in Theodolite when both plates are clamped

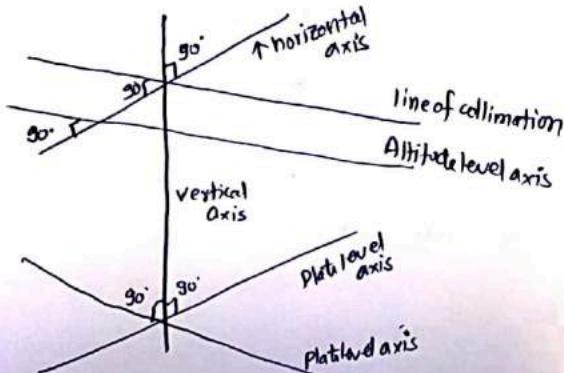

### Fundamental lines of Theodolite

① vertical axis ② Horizontal axis (Trunion axis)

③ axis of plate level ④ line of collimation

⑤ bubble line of Altitude

• when the Theodolite is in proper adjustment following condition should be satisfied.

- ① Horizontal circle  $\perp$  vertical axis
- ② vertical axis must pass through the centre of graduated horizontal circle
- ③ vertical circle  $\perp$  horizontal axis
- ④ horizontal axis must pass through centre of vertical circle
- ⑤ Tangent to plate bubble tube must be  $\perp$  vertical axis.
- ⑥ Line of sight must be perpendicular to transit axis (trunion axis) or horizontal axis
- ⑦ Transit axis must be perpendicular to vertical axis
- ⑧ for horizontal position of telescope and for Altitude bubble at centre, reading on vertical circle must be zero.
- ⑨ Line of sight, horizontal axis, and vertical axis must meet at one point → centre of instruments

### Temporary Adjustment of Theodolite :-

(उत्तर reading लेने की हैरानी में एवं नये station पर)

- 1- setting up over tripod
- 2- centring by plumb bob { aim vertical axis over station mark }
- 3- levelling by levelling screw.
- 4- focussing the eyepiece → to make cross hairs distinct & clear
- 5- focussing the objective → to bring the image of object in plane of cross hairs
- 6- elimination of Parallax.

## Permanent Adjustment of Theodolite :-

aim → to establish relation b/w fundamental lines of Theodolite.

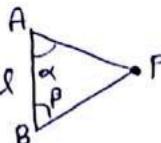

order :- P	C	C	S	B	V.A
Plate level Test	cross-hair Ring Test	collimation in Azimuth Test	Spire Test	bubble Tube adjustment	vertical arc Test
① Plate Level Test	axis of plate level must be perpendicular to vertical axis				
② Cross-hair ring Test	make the <u>vertical cross hair</u> lie in a plane perpendicular to the horizontal axis				
③ collimation in Azimuth Test	make the <u>line of sight</u> perpendicular to horizontal axis				
④ Spire Test	make <u>horizontal axis</u> perpendicular to vertical axis.				
⑤ Bubble Tube adjustment	make <u>telescope bubble central</u> when line of sight is horizontal				
⑥ Vertical arc Test	make the <u>vertical circle indicator zero</u> when line of sight is perpendicular to the vertical axis				

## measurement of Horizontal angle :-

① By repetition method	<ul style="list-style-type: none"> <li>when accuracy is needed beyond least count of instrument with a coarsely graduated circle.</li> <li>more accurate, less error</li> <li>measurement of simple angle</li> <li>horizontal Angle measure several times add them, &amp; divide by no. of repetition, it gives finer degree than least count.</li> </ul>
② By Reiteration method	<ul style="list-style-type: none"> <li>prefer in Triangulation.</li> <li>where no. of angles may be required at one station by the instrument with finely graduated circle.</li> </ul>

Traverse  $\rightarrow$  series of connected lines whose length and direction are measured in field

Traverse principle  $\rightarrow$  (AB,  $\alpha$ , B) known

Length of one side (AB) measured, location of 3rd point is measured after measuring 2 directions (angles)  $\alpha, \beta$

### field work in Theodolite Traverse :-

- ① Reconnaissance
- ② Selection & marking of station
- ③ Measurement of Traverse line (Linear measurement)
- ④ Angular details (Angles)
- ⑤ Picking up details

note:- earlier when distance measuring - Instrument were not there, we used Triangulation.  
Triangulation  $\rightarrow$  one baseline measure then all angles measured to get lengths of other lines

### Angular measurement in Theodolite Traverse :-

① Loose needle (free needle) method	<ul style="list-style-type: none"> <li>Less accurate</li> <li>magnetic bearing of <u>each line</u> is measured at each station</li> </ul>
② fast needle method	<ul style="list-style-type: none"> <li>more accurate than 1st method</li> <li>used in field</li> <li>only magnetic bearing of 1st line measured and with help of <u>included angle</u> we can get magnetic bearing of all other lines.</li> </ul>
③ method of Included Angle	<ul style="list-style-type: none"> <li>most commonly used method</li> <li>magnetic bearing of any line (generally 1st) is measured and all included angles are measured</li> </ul> <p>note:- All angles are measured in clockwise direction because Theodolite graduation increases in clockwise direction.</p>

### ④ method of direct angle

- similar to included angle method
- for open traverse
- in this diral angle or angle to the right is measured.

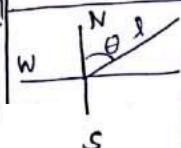

### ⑤ method of deflection angle

- for open traverse
- conducted for survey of roads, railways, canal, pipelines where traverse line make small deflection angle

note:- for n.no. of stations  $\angle FB = 'n-1'$   
 $\angle BB_1 = 'n-1'$

$$\text{Latitude} = l \cos \theta = L$$

$$\text{Departure} = l \sin \theta = D$$

for close traverse  $\sum L = 0, \sum D = 0$

$$\text{closing error} = \sqrt{(\sum L)^2 + (\sum D)^2}$$

$$\text{direction of closing error } \delta = \tan^{-1} \left( \frac{\sum D}{\sum L} \right)$$

$$\text{relative error of closure / Relative accuracy or degree of accuracy} = \frac{e}{P} = \frac{\text{closure error}}{\text{perimeter of traverse}}$$

$$= \frac{1}{(P/e)}$$

well conditioned triangle :-  
not less than  $30^\circ$   
not more than  $120^\circ$

### open traverse :- for preliminary survey

- Desirable to avoid it

- Reasons :-
- ① no arithmetic check for field measurement
  - ② no check on position of intermediate points as there is not known position of points (except starting station)

## Adjustment of Traverse / Balancing of traverse

aim: closing error ( $e$ ) = 0

if closing error is within permissible limit -  
traverse should be adjusted hence error -  
is distributed among various sides of -  
traverse such that traverse geometrically closes.

### ① Bowditch method or Compass rule

In this angle & distance measured  
with same precision.

Assumption: closing error introduced  
in traverse are of accidental (random)  
in nature.

$$\left. \begin{array}{l} \text{error in linear measurement } \propto \frac{1}{J_L} \\ \text{error in Angular } " \quad \propto \frac{1}{J_L} \end{array} \right\}$$

$$\left. \begin{array}{l} C_L = \left( \frac{l}{\sum l} \right) \times \sum L \\ C_D = \left( \frac{D}{\sum D} \right) \times \sum D \end{array} \right\}$$

in this  
after  
correction  
both length  
& bearing change

Note: if we compare with transit rule  
Lengths are changed less, angles are  
changed more.

### ② Transit rule

In this angle precision > Length precision

$$\left. \begin{array}{l} C_L = \left( \frac{L}{L_T} \right) \times \sum L \\ C_D = \left( \frac{D}{D_T} \right) \times \sum D \end{array} \right\}$$

$L_T, D_T$   
Some of  
latitude &  
departure  
without  
considering sign.

Note:  
after correction angles are -  
changed less {  $\because$  already measured with  
high precision)  
& lengths are changed more  
(due to less precision)

Note: if either Latitude or Departure = 0  
(Hence line either parallel to x or y)  
Then as per transit rule  $\Rightarrow$  no correction  
in bearing of line.

### ③ Axis method

### ④ Graphical method

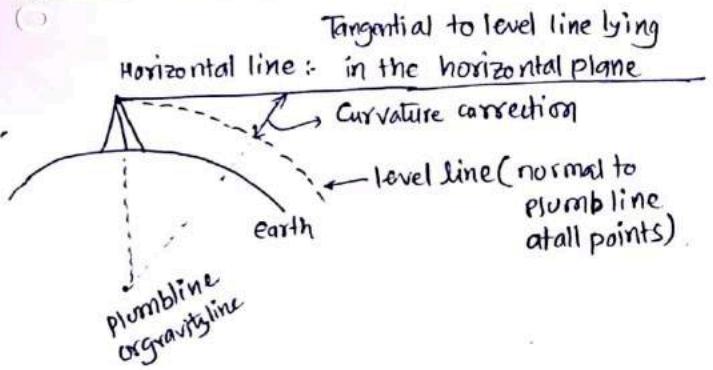

calculation of area of traverse (As per meridian  
distance method)

$$m = m_{\text{previous}} + \frac{D_{\text{current}}}{2} + \frac{D_{\text{previous}}}{2}$$

$$\text{Area} = |\sum m L|$$

Levelling → operation of determining the difference of elevation of points w.r.t each other on surface of earth.

- levelling deals with measurement in vertical plane.
- levelling starts with BS and end with foresight (FS).

Line of sight → Line passing through center of cross hairs and center of eye piece.

Line of collimation : Line of sight when horizontal is called line of collimation. It is achieved when bubble is at the centre in level tube. In such condition axis of bubble tube becomes parallel to line of collimation.

Axis of Telescope : It is line joining the optical centre of objective to the centre of eyepiece.

MSL → for vertical control

adopted by Survey of India for reference is located at Bombay High (Mumbai)

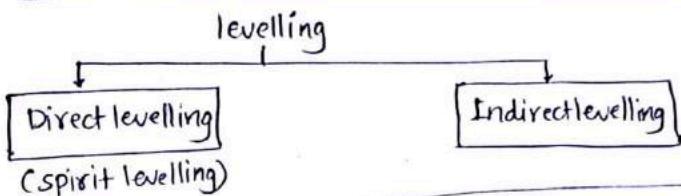

• MSL obtained by averaging the elevation of high tides and low tides at several points for a long period of time (ie 19 years)

$$\text{error} = \frac{\text{measured value} - \text{True value}}{(\Sigma \text{BS} - \Sigma \text{FS})} \quad (\text{last RL} - \text{first RL})$$

1- HI method → check only BS, FS

2- Rise & fall method → check BS, FS + Intermediate sight also

$$\Sigma \text{BS} - \Sigma \text{FS} = \Sigma \text{Rise} - \Sigma \text{fall} = \text{Last RL} - \text{1st RL}$$

(A) Direct levelling :- most commonly used

• spirit Level is fixed to telescope of levelling instrument to make line of sight horizontal then all vertical distance measured w.r.t horizontal line of sight

(B) Indirect levelling :-

(i) Trigonometric levelling (Stadia levelling)

$$\tan \theta = H/D$$

• measure D,  $\theta$  to get H

(ii) Barometric Levelling

• Based on change in atm. pressure. [atm. pressure  $\downarrow$  elevation  $\uparrow$ ]

(iii) Hypsometric Levelling

• These Barometers known as Altimeters, used to find Altitude of aeroplanes

• Based on noting down temp. at which water starts Boiling

[elevation  $\uparrow$  Boiling point  $\downarrow$ ]

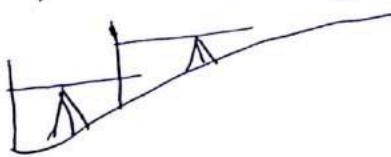

Types of direct Levelling :

(1) Simple Levelling

• to find difference of elevation of 2 points which are visible from a single position of instrument.

(2) Differential (Compound) Levelling

• when 2 points are apart • sep. more than 1 setting of instrument

③ check levelling	<ul style="list-style-type: none"> <li>• Type of differential Levelling</li> <li>• To check elevation which have already plotted.</li> </ul>	<p>① Curvature correction <math>c_c = \frac{km}{2R} = -0.0785d^2</math></p> <p>② Refraction correction <math>c_R = +\frac{1}{7} c_c = +0.0112d^2</math></p> <p><math>R=6370\text{ km}</math></p> <p><math>C = c_c + c_R = -0.0673d^2</math></p>
④ fly levelling	<ul style="list-style-type: none"> <li>• type of differential levelling</li> <li>• to find approx elevation of different points where rapidity is needed &amp; loop precision req.</li> <li>• used for reconnaissance of area for approx level check</li> </ul>	<p>∴ distance of visible horizon <math>d = 3.85\sqrt{h}</math></p> <p>distance of observer from Light house (d)</p> <p><math>d = 3.85(\sqrt{h_1} + \sqrt{h_2})</math></p> <p><math>h_1 \rightarrow</math> Top of light house above sea  <math>h_2 \rightarrow</math> height of observer eye above sea</p>
⑤ profile (longitudinal) levelling	<ul style="list-style-type: none"> <li>• type of differential levelling</li> <li>• to find elevation of ground along a fixed line</li> </ul> <p>Ex. to fix gradient <math>\rightarrow</math> to find earthwork quantities.</p>	<p>Collimation error = True level by formula <math>-0.0673d^2</math></p> $\frac{(h_B-h_A)+(h'_B-h'_A)}{2}$
⑥ cross section levelling	<ul style="list-style-type: none"> <li>• type of differential levelling</li> <li>• To determine the difference of ground surface along the line perpendicular to centre line of road, canal etc.</li> </ul>	<p>note:-</p> <p><math>\text{v.v sml}</math> } effect of corrections</p> <p>• staff reading <math>\text{RL } h_A - 0.0673d^2</math></p> <p>• RL <math>\text{RL } h_A + 0.0673d^2</math></p>
⑦ Precise Levelling	<p>very accurate Differential Levelling in this levelling, "level" is used</p> <ul style="list-style-type: none"> <li>• major component of level</li> </ul> <p>Telescope      Bubble Tube or level tube</p>	<p>sensitivity of Level / Bubble Tube :-</p> <ul style="list-style-type: none"> <li>• express in terms of angle in sec</li> <li>• subtended at a centre of arc of Level tube equal to 1 division of Tube</li> <li>• or angular value of 1 division of bubble tube.</li> </ul>
• Reciprocal levelling :-	<p>① find Difference of elevation of 2 points which are quite apart.</p> <p>when it is difficult to set instrument in mid of 2 points.</p>	$\alpha = \frac{s}{nd} = \frac{\theta}{\eta} = \frac{l}{R}$ <p><math>s \rightarrow</math> difference b/w 2 staff reading  <math>\eta \rightarrow</math> no of division of bubble  <math>D \rightarrow</math> distance  <math>l \rightarrow</math> length of 1 division (if not given assume 2mm)  <math>R \rightarrow</math> radius of curvature of bubble tube</p>
② It eliminates	<p>curvature error      refraction error      collimation error      error in instrument measurement</p> <p>} (not parallax error)</p>	<p>sensitivity <math>\uparrow</math> :- ways?</p>
③ True level difference b/w 2 points	$H = \frac{(h_B-h_A)+(h'_B-h'_A)}{2}$	<p>① Radius of tube (R) <math>\uparrow</math>    ② Length of tube <math>\uparrow</math></p> <p>③ dia of tube <math>\uparrow</math></p> <p>④ viscosity <math>\downarrow</math>      ⑤ surface tension <math>\downarrow</math>      ⑥ roughness <math>\downarrow</math> (smoothening the inner surface of tube)</p>

Tacheometry :- (optical distance measurement method)

flat ground → accuracy of Tacheometry distance low

rough steep ground → more accuracy

→ used in Hill terrain when tape chain & distance surveying is difficult.

method of Tacheometry

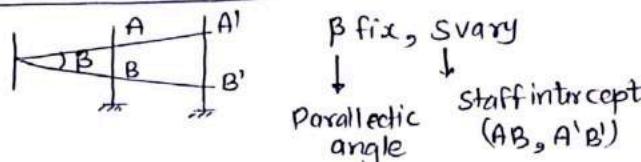

Stadia method  
Tangential  
Rangefinding

### 1- Stadia method

fixed hair method  
( $\beta$  fix,  $s$  vary)

movable hair / substance method  
( $s$  fix,  $\beta$  vary)

#### (A) fixed-hair method :-

Stadia method principle :- {Ratio of perpendicular to Base is constant in Isosceles triangle}

$$D = ks + c$$

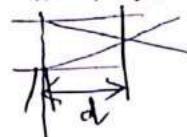

$$D = \left(\frac{f}{i}\right)s + (f + d)$$

$k = \text{multiplying factor/const}$   
 $k = f/i = \text{Stadiamatical factor}$

$f$  → focal length of objective

$i$  → Stadia Interval (interval b/w stadia hair of vertical dist b/w stadia wires or hair distance diagram)

$d$  → horizontal distance b/w optical centre 'O' and vertical axis of tacheometer

Internal focusing Telescope - small  
external " " zero

SMP.

note:- Analeptic lens (convex lens type) → to make additive const=0

#### (B) movable hair method (substance method) :-

( $s$  fix,  $\beta$  vary)

$$D = \frac{ks}{m} + c$$

$$k = f/p \rightarrow \text{pitch of screw}$$

revolution of micrometer

note:- if micrometer reading of drum of diafram = 3.125  
then  $m = 3.125 + 3.450$

$$= 3.125 \\ 3.450$$

Q) If 2 revs in 1cm then  $P = 1 \text{ cm}$

if there is an index error 'e' in the micrometer screw

$$D = \frac{ks}{(m-e)} + c$$

advantage :- • more accurate than fixed hair method  
• more accurate for long sight (only target is to bisected)

disadvantage :- • slow, computation tedious as it comes in denominator  
• very difficult to measure stadia interval(s) accurately

note:- Substancial (Horizontal state) :- rod of fix length horizontally mounted on tripod.

- where chaining not possible because of - undulation and rough country used to find short distance of 200metre.
- Used for measurement of horizontal distance (indirectly)
- In this case minimum refraction error.

#### (C) Tangential method :- (inferior to stadia method)

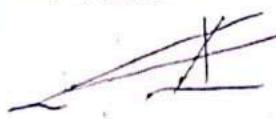

- Used when diaphragm does not have stadia hair, when staff is too far from instrument and it becomes difficult to read to read the staff.
- Stadia wires not used at all. (quite similar to Trigonometric levelling)
- In this observation is made for 2 vertical Angles and staff intercept is obtained with cross wire only.

#### (D) Rangefinding :- use range finder instrument

- only horizontal distance measure, But with the help of level vertical distance can also be measured.
- The Instrument and method based on measurement of either of the base angle or the angle of parallax.

note:- Tilt of staff away from telescope pointing up the hill.

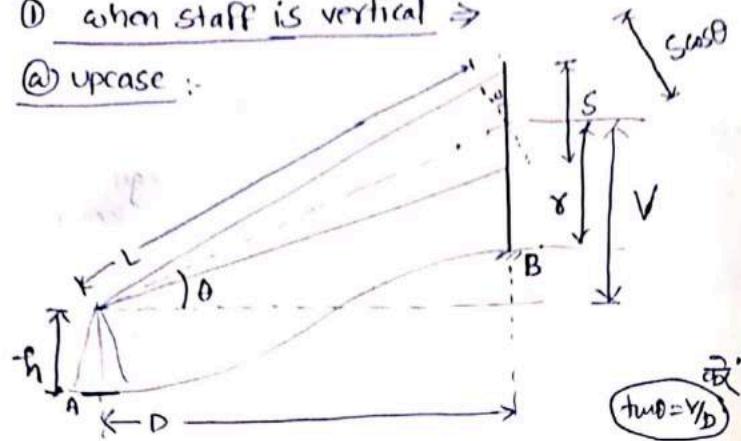

increases the intercept ( $a'b' > ab$ )

## Distance and elevation formula for inclined sight :-

① when staff is vertical  $\Rightarrow$

ⓐ upcase :-

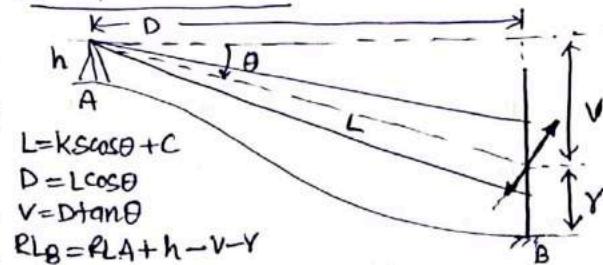

$$L = (KS \cos \theta + c) \quad \rightarrow \text{as per formula}$$

$$\left\{ \begin{array}{l} \text{Horizontal distance } D = LS \cos \theta \\ \text{Vertical } V = D \tan \theta \end{array} \right\}$$

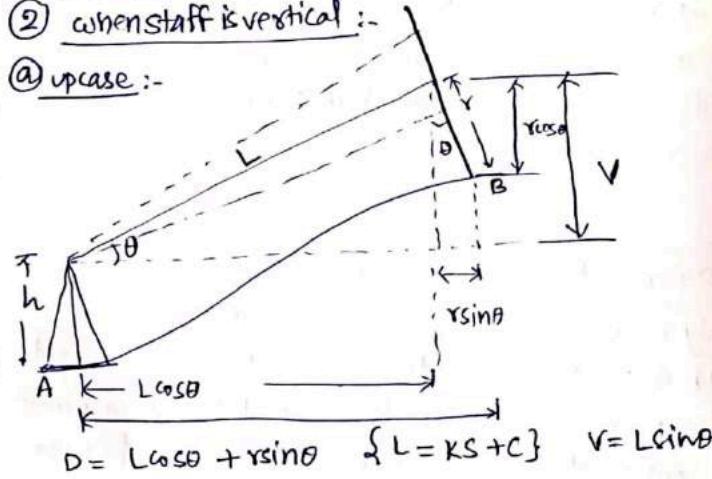

elevation of staff station B = elevation of station (instrument)  
+ h + V - Y

ⓑ depression case :-

② when staff is vertical :-

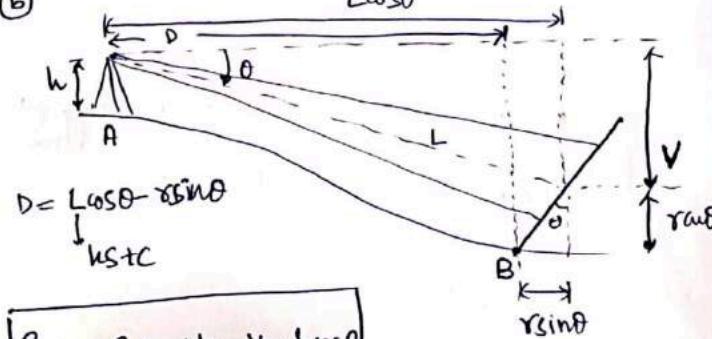

ⓐ upcase :-

$$D = L \cos \theta + r \sin \theta \quad \{ L = KS + C \} \quad V = L \sin \theta$$

$$R_L B = R_L A + h + V - r \cos \theta$$

ⓑ

$$R_L B = R_L A + h - V - r \cos \theta$$

contours : imaginary line passing through points of equal elevation on earth surface

note :- ① Generally contours are not visible on ground except in case of short lines.

② when contours are drawn under water they are known as submarine contours, fathoms, bathymetric curves.

### contouring methods

① Direct method	<ul style="list-style-type: none"> <li>• Tedious, time taken more, accurate</li> <li>• used for small area</li> <li>• for large scale maps where grnd is regular</li> </ul>
-----------------	-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------

② Indirect method or contouring by spot level	<table border="1"> <tr> <td>method of square</td><td> <ul style="list-style-type: none"> <li>• for small area where contours are required at close vertical interval</li> <li>• ground is not very much undulating (plain &amp; gentle slope ground)</li> <li>• area to be surveyed is divided no. of squares</li> </ul> </td></tr> <tr> <td>method of cross-section</td><td>for road, railway, canal survey</td></tr> <tr> <td>Tacheometric method</td><td>in hilly areas</td></tr> </table>	method of square	<ul style="list-style-type: none"> <li>• for small area where contours are required at close vertical interval</li> <li>• ground is not very much undulating (plain &amp; gentle slope ground)</li> <li>• area to be surveyed is divided no. of squares</li> </ul>	method of cross-section	for road, railway, canal survey	Tacheometric method	in hilly areas
method of square	<ul style="list-style-type: none"> <li>• for small area where contours are required at close vertical interval</li> <li>• ground is not very much undulating (plain &amp; gentle slope ground)</li> <li>• area to be surveyed is divided no. of squares</li> </ul>						
method of cross-section	for road, railway, canal survey						
Tacheometric method	in hilly areas						

### uses of contours :-

- 1- Proper & precise location of engineering works as road, railway etc.
- 2- to estimate quantity of cutting, filling (earthwork)
- 3- to estimate the reservoir capacity
- 4- finding profile of country along any direction
- 5- In planning & designing of dam, reservoir.

contour Interval :- The vertical distance b/w consecutive contours.

- It is desirable to have a constant contour interval.
- In case of variable C.I, it gives false impression of relative steepness of ground in different parts

### factors affecting contour interval :-

(i) Scale of Map	scale of map $\propto \frac{1}{C.I}$ if scale is small then interval is kept large so that there is no overlapping of contours.
(ii) Purpose of Map	for detail design $\rightarrow$ small C.I However cost of work increases with small contour interval.
(iii) Nature of ground	for flat ground $\rightarrow$ small C.I Steep slope $\rightarrow$ large C.I
(iv) Time	Time $\propto \frac{1}{C.I}$
(v) funds	Fund $\propto \frac{1}{C.I}$

### Properties of contour lines :-

- ① All points on contour lines  $\rightarrow$  same elevation
- ② where no value is represented  $\rightarrow$  flat terrain
- ③ zero meter contour  $\rightarrow$  coast line
- ④ 2 contour lines don't intersect  
(Except overhanging cliff, cave penetrating hill sides)
- ⑤ Equally spaced contours  $\rightarrow$  uniform slope
- ⑥ Contour well apart  $\rightarrow$  gentle slope
- ⑦ High figure inside  $\rightarrow$  Hill
- ⑧ Low "  $\rightarrow$  depression, lake, pond
- ⑨ irregular contours  $\rightarrow$  uneven ground surface
- ⑩ (watershed or ridge line) & (valley line/wedge line) cross the contours at right angle.

note :- watershed / Ridge line :- line joining highest points of series of hills.

valleyline / wedge line :- line joining lowest points of valley.

### Plane Table :

- ① Instrument for survey by Graphical method in which field observation and plotting done simultaneously.
- ② in this topographic details are mapped in full view hence no chance of missing any details.
- ③ use where greater accuracy is not required.
- ④ for small - medium scale map ( $\frac{1}{10000} - \frac{1}{25000}$ )
- ⑤ This graphical method of producing topographical maps → cartographic surveying.
- ⑥ principle of plane table Survey :-  
an unknown point of interest can be established by measuring its direction from known points

### Advantage of plane Table Survey :-

- ① sighting, plotting simultaneously hence no chance to miss details.
- ② error & mistakes in plotting can be checked by drawing checklines.
- ③ where compass survey is not reliable (area affected by magnetic field), This is very useful.

### Disadvantage :-

- 1- not suited for work in wet climate (rainy season) and in a densely wooded country (area).
- 2- absence of field notes causes inconvenience if survey is to be replotted to some different scale.
- 3- plane table is heavy & awkward to carry and accessories are likely to lost.
- 4- It does not give accurate result.

### Accessories :-

① plane Table board	made of well seasoned wood.
② Tripod	Levelling of Board is done by Tripod Legs
③ Aledade (sighting device)	<ul style="list-style-type: none"> <li>used for sighting the objects &amp; drawing the lines</li> <li>nowadays Telescopic alidade used when points are too high or low to be sighted. The accuracy and range are considerably increased after using it</li> </ul>
④ Trough compass	<ul style="list-style-type: none"> <li>is provided to plot magnetic meridian (N-S direction) to facilitate orientation of plane table in the magnetic meridian.</li> </ul>
⑤ Spirit level or Level tube	<ul style="list-style-type: none"> <li>used for levelling the plane table.</li> <li>It is placed on the board in 2-positions mutually at right angles and the bubbles is centred in each position to make the board horizontal.</li> </ul>
⑥ plumbing fork (U shape)	Used for centring of plane table over station.
⑦ Drawing sheet	Best Quality so that it withstands rubbing.

### Setting up of Plane Table :- (centring - levelling - orientation)

① centring :-	<ul style="list-style-type: none"> <li>done by plumbing fork</li> <li>operation of Bringing plotted station point exactly over the grid station.</li> </ul>
② Levelling	<ul style="list-style-type: none"> <li>done by spirit level / level tube</li> <li>operation of Bringing the plane-table in horizontal plane</li> </ul>

### ③ Orientation

It is operation of keeping table parallel to position, it occurred at the first station.

In such case all the lines plotted will be parallel to the corresponding lines on ground.

methods of orientation :-

#### ① By compass

- can not used where local attraction-suspected.

#### ② By backsighting

- most accurate method of orientation

#### ③ By Resection

- (i) By Back ray
- (ii) By solving 2 point problem
- (iii) By solving 3 point "

method of Plane Table Survey :

① Radiation ② Intersection ③ Traversing ④ Resection

to plot details

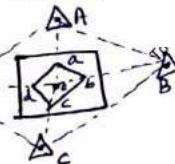

to plot stations

#### ① Radiation

• In this instrument is setup at station and rays are drawn to various stations which are to be plotted.

• many points are plotted provided that points are accessible

• suited : when survey area is small and all stations are clearly visible & accessible from instrument station.

#### ② Intersection

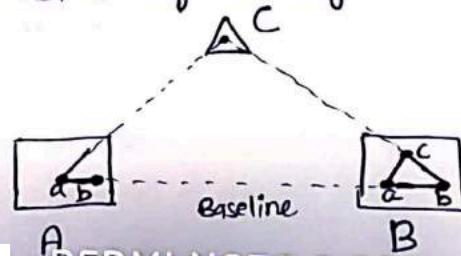

##### [Graphical Triangulation]

• used to plot/locate inaccessible point

• Hilly areas consist of many inaccessible point thus used there.

• In this method 2 stations are selected such that all the other stations to be plotted are visible from these.

• A line joining these 2 stations is called Baseline. The length of Baseline is measured very accurately.

### ③ Traversing

• similar to compass or Theodolite Traversing.  
• Table is set at each of stations in succession → a foresight is taken to the next station and req. distance is cut according to suitable scale.

Ex. when narrow strip of Terrain surveyed (Survey of road, railways)

### ④ Resection

This method of orientation is used/employed when the planetable occupies a position not yet plotted on drawing sheet.

• Resection → process of locating the instrument station occupied by planetable by drawing rays from the stations whose positions are already plotted on drawing sheet.

Resection is done by 3 methods →

#### ① By Back ray

when one of the plotted stations is accessible from the station to the plotted stations

#### ② 2 point Problem

consist of locating the position of a planetable-station on sheet by observation of 2 well-defined points whose positions have already been plotted on the plan.

#### ③ 3 point Problem

can be solved by ① Graphical method ② Trial & error method  
③ Mechanical method ④ Analytical method (Lehman's method)  
⑤ Geometrical construction method

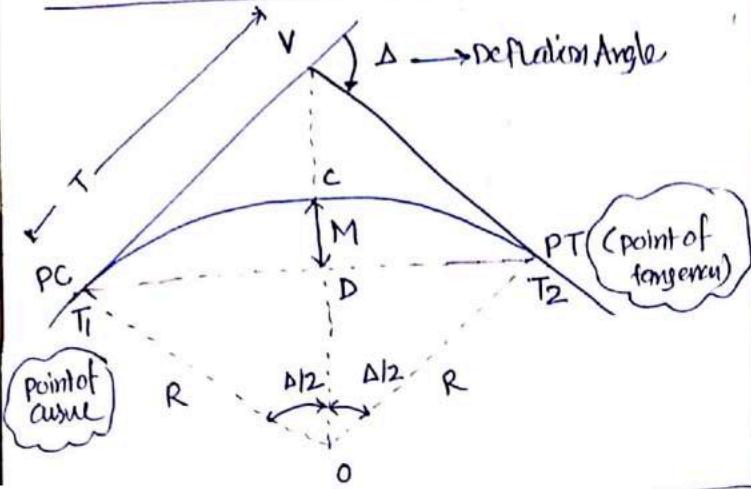

Lehman procedure (3 point problem) :-

- ① Planetable levelled over in station point
- ② 3 resection lines are drawn from 3 well-defined station point
- ③ Triangle of error obtained
- ④ Using Lehman rule an improved position of station point is obtained.
- ⑤ Procedure is repeated till the angle of error is reduced to the point.

Note: if point P is on great circle & middle station is much nearer to P than the other 2 stations → fix is good

Note: The resection position of plane table station from 3 known positions is not determined (unreliable) if station lies on great circle passing through 3 known positions

## Elements of simple circular curve :-

① Length of curve (l)	$R\Delta = R \times \Delta \times \frac{\pi}{180}$ radian
② Tangent Length	$T = R \tan \frac{\Delta}{2}$
③ chainage of tangent Points	$T_1 = \text{chainage of } V - T_1$ $T_2 = \text{chainage of } T_1 + l$
④ Length of long chord ( $T_1$ to $T_2$ )	$2R \sin \frac{\Delta}{2}$
⑤ mid ordinate 'or' versine of curve (M)	$R(1 - \cos \frac{\Delta}{2})$
⑥ External distance or Apex distance ( $VO - CO$ ) = E	$R(\sec \frac{\Delta}{2} - 1)$

note:- ① In transition curve :-

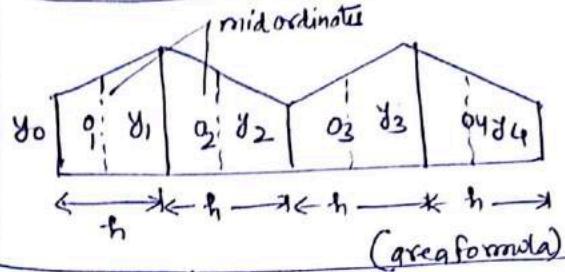

$$\text{Polar deflection angle} = \frac{\text{spherical angle } (\alpha_s)}{3}$$

② Rankine method of Deflection Angle :-  $\Delta_2 = \Delta_1 + \delta_2$

Deflection Angle for any chord ( $\Delta_2$ )

$$= \text{Deflection angle for preceding chord } (\Delta_1) + \text{tangential angle of that chord } (\delta_2)$$

## Measurement of Area & Volume :-

$$\begin{aligned} \text{① mid-ordinate method} \\ &= \left[ \frac{o_1 + o_2 + \dots + o_n}{n} \right] \times (m \cdot h) \\ &= (o_1 + o_2 + \dots + o_n) \times h \end{aligned}$$

$$\begin{aligned} \text{② Avg. ordinate method} \\ &= \text{avg. ordinate} \times \text{Length of base} \\ &= \frac{y_0 + y_1 + \dots + y_n}{(n+1)} \times (m \cdot h) \end{aligned}$$

$$\begin{aligned} \text{③ Trapezoidal rule} \\ \text{(end-area method)} \\ &= \text{more accurate than mid-ordinate method} \\ &= \frac{h}{2} \left[ (y_0 + y_n) + 2(y_1 + y_2 + \dots + y_{n-1}) \right] \end{aligned}$$

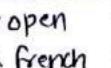

$$\begin{aligned} \text{④ Simpson's 1/3rd rule} \\ \text{(Prismoidal formula)} \\ &= \text{when odd no. of ordinates} \\ &= \frac{h}{3} \left[ (y_0 + y_n) + 4(y_1 + y_3 + \dots + y_{n-2}) + 2(y_2 + y_4 + \dots + y_{n-1}) \right] \end{aligned}$$

note:- Length of Boundaries b/w 2 adjacent ordinates is Parabolic arch.

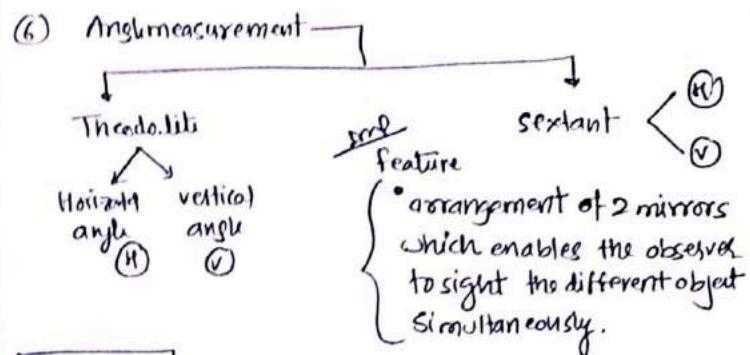

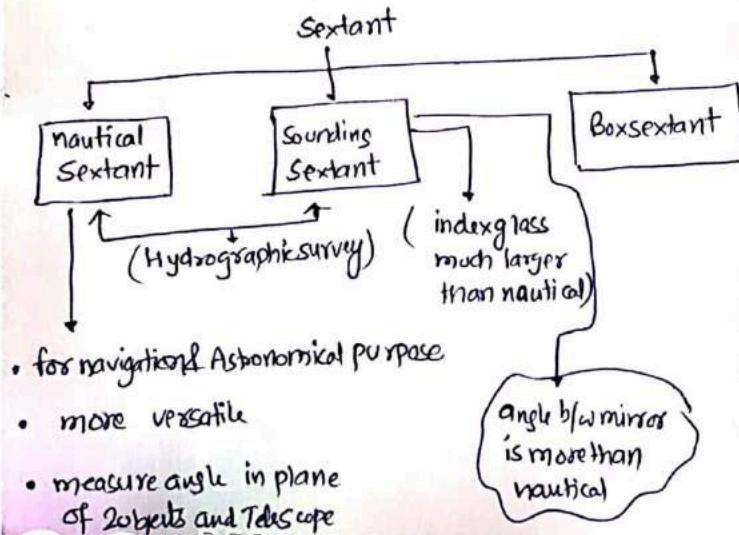

## Instruments

- ① Mining compass :- Theodolite built in compass used for mine survey.
- ② Brunton's compass :- combination of compass & clinometer
- ③ distance measuring instrument :-  
  - pasometer • pedometer • pacing • perambulator
  - odometre (no. of revolutions req.)
  - speedometer
  - substance bar → horizontal distance  
(Baseline of small Triangulation, to fix control point in area)
  - Tellermeter - remote plat. distance
  - Telluro meter - microwave electronic equipment, geodetic principle
  - Geodimeter (25 km से कम के लिए)
  - EDM

## right angle measurement

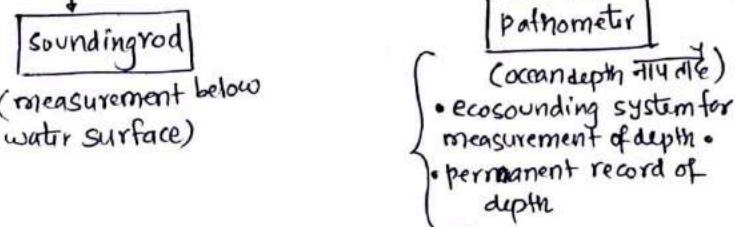

- cross staff  French (45°, 135° also)
- sit square • prism square • rangefinder
- optical square  $\equiv$  Box sextant (used to measure angle)  
box 75mm dia, 40mm deep  
(both → horizontal glass & index glass)

- ⑤ Sextant principle :- 2 mirror → light successively reflect  
then angle b/w 1st & last ray =  $2 \times$  angle b/w mirror  
note:- if angle b/w index glass and horizontal glass =  $40^\circ$   
then horizontal angle b/w 2 points =  $2 \times 40 = 80^\circ$

**clinometer** → measure angle of slope, elevation, depression wrt gravity direction.

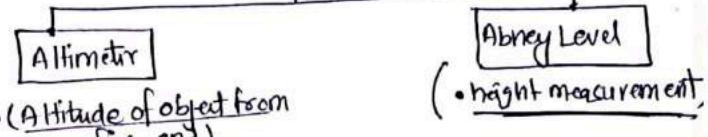

## Depth measurement

## velocity measurement of water

Prismeter  
Current meter

## Altitude measurement

- ⑩ Tangent clinometer :- to get difference in elevation between points.  
  - Indian pattern clinometer
  - plane survey फैसला टेबल

- ⑪ Parallax :- Image formed by object is not in plane of cross hair due to height of object

- ⑫ Pantograph :- enlarge/reduce a already drawn plan.

- ⑬ Hand Level :- levelling instrument held in hand, approx. determination of elevation.

- ⑭ Dumpy level → only Horizontal Angle,  
Telescope → nonmovable

- ⑮ Wye level → telescope movable

## Theory of errors :-

Error = measure value - True value  
 Residual                          True value  
                                     most probable value  
                                     close to true value  
                                     than many other

True error = observe value - True value  
 Residual error = observe value - MPV  
 ( $x_i$ )                            ( $x_i$ )

## ② Adjust the following Ansle closing horizons ?

$$P = 110^{\circ} 20' 48''$$

$$Q = 92^{\circ} 30' 12''$$

$$R = 56^{\circ} 12' 00''$$

$$S = 100^{\circ} 57' 04''$$

$$\sum = 360^{\circ} 00' 04''$$

hence correction = (-4'')

$$\therefore c_1 : c_2 : c_3 : c_4 = \frac{1}{4} : \frac{1}{1} : \frac{1}{2} : \frac{1}{3}$$

$$\therefore c_1 : c_2 : c_3 : c_4 = 3 : 12 : 6 : 4$$

Weight  
Trust  
Sett  
Corr

$$\therefore c_1 = -\frac{3}{25} \times 4'' = -0.48'' c_3 = -$$

$$c_2 = \frac{-12}{25} \times 4'' \quad c_4 = -$$

$$\therefore CP = 110^{\circ} 20' 48'' - 0.48'' = 110^{\circ} 20' 47.52''$$

weight of quantity . (its relative trustworthiness of set of observation.)

$$\text{Sum/difference} \Rightarrow \frac{1}{\frac{1}{w_1} + \frac{1}{w_2}}$$

$$kW \rightarrow \frac{w}{k^2}$$

$$\frac{w}{k} \rightarrow k^2 \times w$$

$$k+w \rightarrow w$$

$$k-w \rightarrow w$$

- The weight of the weighted arithmetic mean of observation is equal to sum of the weights of observations.

$$\text{Ex. } 5.48 \quad S = \frac{.01}{2} \quad e = \delta_{1/2}$$

$$5.0 \quad S = \frac{.1}{2} \quad e = \delta_{1/2}$$

	max. error	Probable error
$x+y$	$\delta_x + \delta_y$	$\sqrt{(\epsilon_x)^2 + (\epsilon_y)^2}$
$x-y$	$\delta_x + \delta_y$	$\sqrt{(\epsilon_x)^2 + (\epsilon_y)^2}$
$xy$	$x\delta_y + y\delta_x$	$\sqrt{(x\epsilon_y)^2 + (y\epsilon_x)^2}$
$\frac{x}{y}$	$y\delta_x + x\delta_y$	$\sqrt{\left(\frac{y\epsilon_x}{y^2}\right)^2 + \left(\frac{x\epsilon_y}{y^2}\right)^2}$

① find Probable value of A = ?

$$2A = 20^{\circ} 10' \quad \text{weight} = 2$$

$$4A = 40^{\circ} 10' \quad \text{weight} = 3$$

$$\text{sum: } 2 \times [2 \times 2A] = (2 \times 20^{\circ} 10') \times 2$$

$$3 \times [4 \times 4A] = (4 \times 40^{\circ} 10') \times 3$$

$$56A = \underline{\hspace{2cm}}$$

Q.F.E. = 5 - 2 + 2 + 0

## Photogrammetry :-

Napier rule :- Applicable for right angled spherical Triangle

Spherical Excesses :- sum of angle of spherical Triangle exceeds 180°

Astronomical Triangles :-

Vertices of Astronomical Triangle (ZMP)

Zenith

Celestial Body

Pole

Note:-

(i) path of stars is the result of diurnal motion of earth.

(ii) points at which sun declination is maximum are known as → solstice

(iii) zero → vernal Equinox.

(i) Aerial Survey steps : (i) Reconnaissance  
 (ii) establish ground control (iii) flight planning  
 (iv) Photography (v) paperwork including Computing & planning

2- Principle point :- A point where perpendicular from the optical centre of lens meets photograph.

3- Plum point :- a point where vertical through the optical centre of lens meets photograph.

4- Perspective point :- A point where rays from the object converge.

5- Index mosaic photograph are pasted on fibre board and whole assembly is photographed again.

6- Index mosaic are not true planimetric representation of the area.

$$\frac{x_a}{XA} = \frac{f}{H-h_a} = \text{scale} = \frac{\text{map distance}}{\text{true distance}}$$

f → camera focal length

h → height of gsd above MSL

H → height of exposure station above MSL

$$L_{AB} = \sqrt{(X_A - X_B)^2 + (Y_A - Y_B)^2}$$

$$h_{avg} = \frac{h_A + h_B}{2}$$

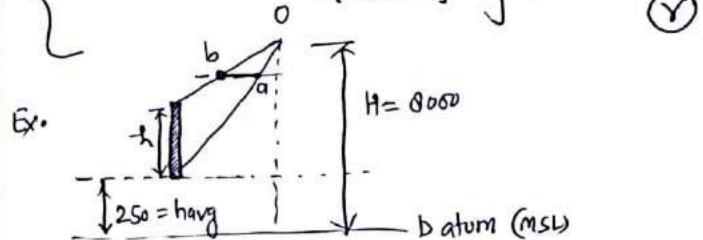

$$\text{datum scale} \Rightarrow \text{Harmat } h=0 \therefore S = f/H-0$$

$$d = \frac{h_h}{H - h_{avg}}$$

height of Tower
height of object above MSL

relief Displacement = top-bottom

relief displacement ∝ focal length  
 ∝ dist. of object from Nadir point

no. of photographs in each strip •

$$N_1 = \frac{L_1 \text{ (Length)}}{(1 - P_w) \times S \times l} + 1$$

%/ lap in long direction      length of photo in direction of flight  
10000 (if 1:10000)

$$\text{no. of strips} \Rightarrow N_2 = \frac{L_2}{(1 - P_w) S l} + 1$$

(1) Geometrical centre of photograph is defined by intersection of two lines joining the fiducial marks.

(2) map → orthogonal projection  
 photo → central "

(3) Drift → Lateral shifting of photograph

(4) Crab → (occurred while avoiding Drift)  
 ↳ when aircraft is not orientated with Flight line, photographs are not parallel to flight line.

drift  
18/4/2020
