# **Arithmetic Progressions**

### • The Concept of Arithmetic Progression

- An arithmetic progression is a list of numbers in which the difference between any two consecutive terms is equal.
- o In an AP, each term, except the first term, is obtained by adding a fixed number called common difference to the preceding term.
- o The common difference of an AP can be positive, negative or zero.

## Example 1:

1.

1. 1. 4 6 9 is an AP whose first term and common difference are 3 and 3 respectively.

2.

4.

5. 3. 4 is an AP whose first term and common difference are –7 and 0 respectively.

o The general form of an AP can be written as a, a + d, a + 2d, a + 3d ..., where a is the first term and d is the common difference.

A given list of numbers i.e.,  $a_1$ ,  $a_2$ ,  $a_3$  ... forms an AP if  $a_{k+1} - a_k$  is the same for all values of k.

## Example 2:

Which of the following lists of numbers forms an AP? If it forms an AP, then write its next three terms.

$$(a)$$
  $-4$ ,  $0$ ,  $4$ ,  $8$ , ...

#### **Solution:**

$$(a)$$
  $-4$ ,  $0$ ,  $4$ ,  $8$ , ...

$$a_2 - a_1 = 0 - (-4) = 4$$

$$a_3 - a_2 = 4 - 0 = 4$$

$$a_4 - a_3 = 8 - 4 = 4$$

$$a_{n+1} - a_n = 4$$
; for all values of  $n$ 

Therefore, the given list of numbers forms an AP with 4 being its common difference.

The next three terms of the AP are 8 + 4 = 12, 12 + 4 = 16, 16 + 4 = 20 Hence, AP: -4, 0, 4, 8, 12, 16, 20 ...

**(b)** 2, 4, 8, 16, ...  

$$a_2 - a_1 = 4 - 2 = 2$$
  
 $a_3 - a_2 = 8 - 4 = 4$   
 $a_3 - a_2 \neq a_2 - a_1$ 

Therefore, the given list of numbers does not form an AP.

#### • The terminology related to arithmetic progression

- An arithmetic progression is a list of numbers in which each term is obtained by adding a fixed number to the preceding term except the first term.
- The fixed number is called the common difference (*d*) of the A.P. The common difference can be either positive or negative or zero.
- The general form of an A.P.
- a, (a + d), (a + 2d), (a + 3d), ..., [a + (n 1)d], ... where a is the first term and d is common difference
- Type of AP
- Finite AP: The APs have finite number of terms.
- Infinite AP: The APs have not finite number of terms.
- In an A.P., except the first term, all the terms can be obtained by adding the common difference to the previous term.
- In an A.P., except the last term, all the terms can be obtained by subtracting the common difference from its subsequent term.

#### **Example:**

Find the first four terms of an A.P. whose first term is 9 and the common difference is 6.

#### Solution:

$$a = 9$$
,  $d = 6$   
 $a_2 = a + d = 9 + 6 = 15$   
 $a_3 = a + 2d = 9 + 2 \times 6 = 9 + 12 = 21$   
 $a_4 = a + 3d = 9 + 3 \times 6 = 9 + 18 = 27$ 

The first four terms are 9, 15, 21, 27.

### $n^{\text{th}}$ term of an AP

The  $n^{\text{th}}$  term  $(a_n)$  of an AP with first term a and common difference d is given by  $a_n = a + (n-1) d$ .

Here,  $a_n$  is called the general term of the AP.

#### • n<sup>th</sup> term from the end of an AP

The  $n^{\text{th}}$  term from the end of an AP with last term l and common difference d is given by l - (n-1) d.

### **Example:**

Find the 12<sup>th</sup> term of the AP 5, 9, 13 ...

### **Solution:**

Here, 
$$a = 5$$
,  $d = 9 - 5 = 4$ ,  $n = 12$   
 $a_{12} = a + (n - 1) d$   
 $= 5 + (12 - 1) 4$   
 $= 5 + 11 \times 4$   
 $= 5 + 44$   
 $= 49$ 

#### Sum of n terms of an AP

- The sum of the first *n* terms of an AP is given by Sn=n22a+n-1d, where *a* is the first term and *d* is the common difference.
- o If there are only *n* terms in an AP, then Sn=n2a+l, where  $I = a_n$  is the last term.

#### Example:

Find the value of 2 + 10 + 18 + .... + 802.

Solution:

2, 10, 18... 802 is an AP where a = 2, d = 8, and l = 802.

Let there be *n* terms in the series. Then,

 $a_n = 802$ 

 $\Rightarrow$  a + (n - 1) d = 802

 $\Rightarrow$  2 + (n - 1) 8= 802

 $\Rightarrow 8(n-1) = 800$ 

 $\Rightarrow n-1=100$ 

 $\Rightarrow n = 101$ 

Thus, required sum = n2a+l = 10122+802 = 40602

## • Properties of an Arithmetic progression

- o If a constant is added or subtracted or multiplied to each term of an A.P. then the resulting sequence is also an A.P.
- o If each term of an A.P. is divided by a non-zero constant then the resulting sequence is also an A.P.

#### Arithmetic mean

For any two numbers a and b, we can insert a number A between them such that a, A, b is an A.P. Such a number i.e., A is called the arithmetic mean (A.M) of numbers a and b and it is given by  $A = \frac{a+b}{2}$ .

 $\circ$  For any two given numbers a and b, we can insert as many numbers between them as we want such that the resulting sequence becomes an A.P.

Let  $A_1$ ,  $A_2$ ...  $A_n$  be n numbers between a and b such that a,  $A_1$ ,  $A_2$ ...  $A_n$ , b is an A.P. Here, common difference (d) is given by  $\frac{b-a}{n+1}$ .

### **Example:**

Insert three numbers between -2 and 18 such that the resulting sequence is an A.P.

#### **Solution:**

Let  $A_1$ ,  $A_2$ , and  $A_3$  be three numbers between -2 and 18 such that -2,  $A_1$ ,  $A_2$ ,  $A_3$ , 18 are in an A.P.

Here, 
$$a = -2$$
,  $b = 18$ ,  $n = 5$ 

$$\therefore 18 = -2 + (5 - 1) d$$

$$\Rightarrow$$
 20 = 4  $d$ 

$$\Rightarrow d = 5$$

Thus, 
$$A_1 = a + d = -2 + 5 = 3$$

$$A_2 = a + 2d = -2 + 10 = 8$$

$$A_3 = a + 3d = -2 + 15 = 13$$

Hence, the required three numbers between –2 and 18 are 3, 8, and 13.
